

MICROBIAL DELIVERY SYSTEM

Priority Information

5 The present application is a divisional of U.S. Patent Application Serial Number 09/731,375 entitled "Bacterial Polypeptide Delivery" filed December 6, 2000 which claims priority under 35 U.S.C. 119(c) to U.S. Provisional Patent Application Serial Number 60/195,035 entitled "Bacterial Polypeptide Delivery" filed April 6, 2000.

Related Applications

10 The present invention is generally in the area of controlled delivery of antigens for use in vaccination or induction of tolerance to allergens, and in particular relates to cellular delivery of proteins and polypeptides. This application is related to U.S.S.N. 60/169,330 entitled
15 "Controlled Delivery of Antigens" filed Dec. 6, 1999; U.S.S.N. 09/141,220 entitled "Methods and Reagents for Decreasing Clinical Reaction to Allergy" filed Aug. 27, 1998; U.S.S.N. 09/455,294 entitled "Peptide Antigens" filed December 6, 1999; U.S.S.N. 09/494,096 filed January 28, 2000 entitled "Methods and Reagents for Decreasing Clinical Reaction to Allergy"
20 by Bannon et al.; and U.S.S.N. 09/527,083 entitled "Immunostimulatory Nucleic Acids and Antigens" by Caplan filed March 16, 2000; the teachings of which are all incorporated herein by reference in their entirety.

Background of the Invention

25 Allergic reactions pose serious public health problems worldwide. Pollen allergy alone (allergic rhinitis or hay fever) affects about 10-15% of the population, and generates huge economic costs. For example, reports estimate that pollen allergy generated \$1.8 billion of direct and indirect expenses in the United States in 1990 (*Fact Sheet*, National Institute of Allergy and Infectious Diseases; McMenamin, *Annals of Allergy* 73:35, 1994). Asthma, which can be

triggered by exposure to antigens, is also a serious public health problem, and like anaphylactic allergic reactions, can lead to death in extreme cases. Asthma currently accounts for millions of visits yearly to hospitals and is increasing in frequency. The only treatment currently available is for alleviation of symptoms, for example, to relieve constriction of airways. More serious than
 5 the economic costs associated with pollen and other inhaled allergens (e.g., molds, dust mites, animal danders) is the risk of an anaphylactic allergic reaction observed with allergens such as food allergens, insect venoms, drugs, and latex.

Allergic reactions result when an individual's immune system overreacts, or reacts inappropriately, to an encountered antigen. Typically, there is no allergic reaction the first time
 10 an individual is exposed to a particular antigen. However, it is the initial response to an antigen that primes the system for subsequent allergic reactions. In particular, the antigen is taken up by antigen presenting cells (APC; e.g., macrophages and dendritic cells) that degrade the antigen and then display antigen fragments to T cells. T cells, in particular CD4⁺ "helper" T-cells, respond by secreting a collection of cytokines that have effects on other immune system cells.
 15 The profile of cytokines secreted by responding CD4⁺ T cells determines whether subsequent exposures to the antigen will induce allergic reactions. Two classes of CD4⁺ T cells (Th1 and Th2) influence the type of immune response that is mounted against an antigen.

Th2 cells can secrete a variety of cytokines and interleukins including IL-4, IL-5, IL-6, IL-10 and IL-13. One effect of IL-4 is to stimulate the maturation of B cells that produce IgE
 20 antibodies specific for the antigen. Allergic responses to allergens are characterized by the production of antigen-specific IgE antibodies which are dependent on help from IL-4 secreting CD4⁺ T cells. These antigen-specific IgE antibodies attach to receptors on the surface of mast cells, basophils and eosinophils, where they act as a trigger to initiate a rapid allergic reaction upon the next exposure to antigen. When the individual encounters the antigen a second time,
 25 the antigen is quickly bound by these surface-associated IgE molecules. Each antigen typically has more than one IgE binding site, so that the surface-bound IgE molecules quickly become crosslinked to one another through their simultaneous (direct or indirect) associations with antigen. Such cross-linking induces mast cell degranulation, resulting in the release of

histamines and other substances that trigger allergic reactions. Individuals with high levels of IgE antibodies are known to be particularly prone to allergies.

Current treatments for allergies involve attempts to “vaccinate” a sensitive individual against a particular allergen by periodically injecting or treating the individual with a crude suspension of the raw allergen. The goal, through controlled administration of known amounts of antigen, is to modulate the IgE response mounted in the individual. If the therapy is successful, the individual’s IgE response is diminished, or can even disappear. However, the therapy requires several rounds of vaccination, over an extended time period (3-5 years), and very often does not produce the desired results. Moreover, certain individuals suffer anaphylactic reactions to the vaccines, despite their intentional, controlled administration.

Clearly, there is a need for treatments and preventive methods for patients with allergies to allergens that elicit serious allergic responses including anaphylaxis.

Summary of the Invention

The present invention provides methods and compositions for modulating the immune response in a subject. It is an aspect of the present invention to provide a method of treating or preventing undesirable allergic reactions and anaphylactic allergic reactions to allergens in a subject. Methods of the present invention involve administering to subjects, microorganisms that express or produce allergens of interest. Without being limited to the proposed mechanism of action, after administration the microorganisms are taken up by antigen-presenting cells in the subject where the expressed antigens are released. After being processed inside the antigen-presenting cells and displayed on the cell surface, the processed antigens activate T-cell mediated immune responses. Use of genetically modified microorganisms to express and deliver allergens to a subject therefore reduces the exposure of the allergens to the subject’s IgE antibodies, which lead to allergic reactions and possibly anaphylaxis. The present invention therefore reduces the risk of anaphylaxis during immunotherapy. Furthermore, the microorganisms may act as a natural adjuvant to enhance desirable Th1-type immune responses.

In a preferred embodiment, microorganisms are genetically modified to express selected polypeptides or proteins, and are used as delivery vehicles in accordance with the present invention. Such microorganisms include but are not limited to bacteria, viruses, fungi (including yeast), algae, and protozoa. Generally, preferred microorganisms for use in accordance with the present invention are single cell, single spore or single virion organisms. Additionally, included within the scope of the present invention are cells from multi-cellular organisms which have been modified to produce a polypeptide of interest.

In a particularly preferred embodiment, bacteria or yeast are used as microorganisms to express and deliver allergenic proteins to individuals to treat or prevent allergic responses, including anaphylactic allergic responses, to the allergens. Gram-positive and gram-negative bacteria may be used in the present invention as delivery vehicles. Antigens expressed by the bacteria may be secreted or non-secreted. Secretion of proteins may involve secretion into the cellular medium. For gram-negative bacteria and yeast, secretion may involve secretion into the periplasm. Secretion of polypeptides may be facilitated by secretion signal peptides. In certain preferred embodiments microorganisms expressing allergenic compounds may be administered to subjects in compositions as attenuated microorganisms, non-pathogenic microorganisms, non-infectious microorganisms, or as killed microorganisms. Preferably, the killed microorganisms are killed without degrading the antigenic properties of the polypeptides.

In another preferred embodiment, the allergens utilized are allergens found in foods, venom, drugs and a rubber-based products. Particularly preferred protein allergens are found in foods and venoms that elicit anaphylactic allergic responses in subjects who are allergic to the allergens. Included in the present invention are peptides and polypeptides whose amino acid sequences are found in the proteins allergens in nature. Also included in the present invention are allergens that have modifications that reduce the ability of the peptides, polypeptides and proteins to bind and crosslink IgE antibodies. Also included in the present invention are non-peptide allergens that are produced by microorganisms and include for example antibiotics such as penicillin.

In another aspect of the invention, compositions for use in treating or preventing allergic and anaphylactic allergic responses in a subject comprise microorganisms that have been engineered

by the hand of man, and preferably by the introduction of one or more introduced nucleic acids, to produce allergens in accordance with the present invention. In certain preferred embodiments, the produced allergens are peptides, polypeptides, or proteins encoded by the introduced nucleic acids(s).

Brief Description of Figures

Figure 1. Experiments designed to determine the optimal temperature for heat-killing bacteria (*E. coli*) are depicted in graphic form. The number of surviving colonies in aliquots of samples are shown as a function of temperature (Celsius).

Figure 2. Determination of protein produce per cell. The optical density (O.D.) of the HIS-tagged Ara h 2 allergen was determined from an immunoblot where different concentrations of *E. coli* extract has been electrophoresed on SDS-PAGE gels. The allergen O.D. was used to estimate the amount of protein produced by that extract.

Figure 3. Results of ELISA analysis of Ara h 2-specific IgG antibodies produced in mice following injection of *E. coli* producing Ara h 2. IgG1 is on the left and IgG2a is on the right.

Figure 4. Results of ELISA analysis of Ara h 3-specific IgG antibodies produced in mice following injection of *E. coli* producing Ara h 3. IgG1 is on the left and IgG2a is on the right.

Figure 5 shows an example of how IgE binding epitopes were mapped to a specific amino acid sequence on the Ara h 1 allergen. In particular, Figure 5 depicts twenty-two 10-mer peptides (SEQ ID NOs. 45-66) that span amino acid residues 82-133 (SEQ ID NO. 44) of the Ara h 1 allergen (SEQ ID NO. 2). This region of the Ara h 1 allergen includes epitopes 4, 5, 6, and 7, as identified in Table 1.

Figure 6 shows an example of how IgE binding epitopes were mapped to a specific amino acid sequence on the Ara h 2 allergen. In particular, Figure 6 depicts seven 10-mer peptides (SEQ ID NOs. 68-74) that span amino acid residues 55-76 (SEQ ID NO. 67) of the Ara h 2 allergen (SEQ ID NO. 4). This region of the Ara h 2 allergen includes epitopes 6 and 7 as identified in Table 2.

Figure 7 shows an example of how IgE binding epitopes were mapped to a specific amino acid sequence on the Ara h 3 allergen. In particular, Figure 7 depicts six 15-mer peptides (SEQ ID NOs. 76-81) that span amino acid residues 299-321 (SEQ ID NO. 75) of the Ara h 3 allergen (SEQ ID NO. 6). This region of the Ara h 3 allergen includes epitope 4 as identified in Table 3.

Figure 8 shows the effect the modified Ara h 2 protein has on IgE binding.

Figure 9 shows the results of T cell proliferation assays using the wild-type and modified Ara h 2 protein.

Definitions

“Allergen”: An “allergen” is an antigen that (i) elicits an IgE response in an individual; and/or (ii) elicits an asthmatic reaction (e.g., chronic airway inflammation characterized by eosinophilia, airway hyperresponsiveness, and excess mucus production), whether or not such a reaction includes a detectable IgE response). Preferred allergens for the purpose of the present invention are peptide, polypeptide and protein allergens. An exemplary list of protein allergens is presented as an Appendix. This list was adapted from <ftp://biobase.dk/pub/who-iuis/allergen.list> (updated on March 1, 2000), which provides lists of known allergens. Other preferred allergens are chemical compounds such as small molecules that are produced by proteins. In some embodiments, an allergen is a subset of antigens which elicits IgE production in addition to other isotypes of antibodies.

“Allergic reaction”: An allergic reaction is a clinical response by an individual to an antigen. Symptoms of allergic reactions can affect cutaneous (e.g., urticaria, angioedema, pruritus), respiratory (e.g., wheezing, coughing, laryngeal edema, rhinorrhea, watery/itching eyes) gastrointestinal (e.g., vomiting, abdominal pain, diarrhea), and/or cardiovascular (if a systemic reaction occurs) systems. For the purposes of the present invention, an asthmatic reaction is considered to be a form of allergic reaction. A decreased allergic reaction is characterized by a decrease in clinical symptoms following treatment of symptoms associated with exposure to an allergen, which can involve respiratory, gastrointestinal, skin, eyes, ears and mucosal surfaces in general.

“Anaphylactic antigen”: An “anaphylactic antigen” according to the present invention is an antigen (or allergen) that is recognized to present a risk of anaphylactic reaction in allergic individuals when encountered in its natural state, under natural conditions. For example, for the purposes of the present invention, pollens and animal danders or excretions (e.g., saliva, urine) are not considered to be anaphylactic antigens. On the other hand, food antigens, insect antigens, drugs, and rubber (e.g., latex) antigens latex are generally considered to be anaphylactic antigens. Food antigens are particularly preferred anaphylactic antigens for use in the practice of the present invention. Particularly interesting anaphylactic antigens are those (e.g., nuts, seeds, and fish) to which reactions are commonly so severe as to create a risk of death.

“Anaphylaxis” or “anaphylactic reaction”, as used herein, refers to an immune response characterized by mast cell degranulation secondary to antigen-induced cross-linking of the high-affinity IgE receptor on mast cells and basophils with subsequent mediator release and the production of pathological responses in target organs, e.g., airway, skin digestive tract and cardiovascular system. As is known in the art, the severity of an anaphylactic reaction may be monitored, for example, by assaying cutaneous reactions, puffiness around the eyes and mouth, and/or diarrhea, followed by respiratory reactions such as wheezing and labored respiration. The most severe anaphylactic reactions can result in loss of consciousness and/or death.

“Antigen”: An “antigen” is (i) any compound or composition that elicits an immune response; and/or (ii) any compound that binds to a T cell receptor (e.g., when presented by an MHC molecule) or to an antibody produced by a B-cell. Those of ordinary skill in the art will

appreciate that an antigen may be collection of different chemical compounds (e.g., a crude extract or preparation) or a single compound (e.g., a protein). Preferred antigens are peptide, polypeptide or protein antigens. In some embodiments, an antigen is a molecule that elicits production of antibody (a humoral response) or an antigen-specific reaction with T cells (a cellular response).

“Antigen presenting cells”: “Antigen presenting cells” or APCs” include known APCs such as Langerhans cells, veiled cells of afferent lymphatics, dendritic cells and interdigitating cells of lymphoid organs. The term also includes mononuclear cells such as lymphocytes and macrophages which take up polypeptides and proteins according to the invention. In some embodiments, an antigen presenting cell (an APC) is a cell which processes and presents peptides to T cells to elicit an antigen-specific response.

“Attenuation”: “Attenuation” of microorganisms as used herein refers to the manipulation of the microorganisms so that the microorganisms do not induce significant toxic reactions in individuals or laboratory test animals. The manipulations include genetic methods and are well known in the art.

An epitope is a binding site including an amino acid motif of between approximately six and fifteen amino acids which can be bound by either an immunoglobulin or recognized by a T cell receptor when presented by an antigen presenting cell in conjunction with the major histocompatibility complex (MHC). A linear epitope is one where the amino acids are recognized in the context of a simple linear sequence. A conformational epitope is one where the amino acids are recognized in the context of a particular three dimensional structure. An immunodominant epitope is one which is bound by antibody in a large percentage of the sensitized population or where the titer of the antibody is high, relative to the percentage or titer of antibody reaction to other epitopes present in the same protein.

“IgE binding site”: An IgE binding site is a region of an antigen that is recognized by an anti-antigen IgE molecule. Such a region is necessary and/or sufficient to result in (i) binding of the antigen to IgE; (ii) cross-linking of anti-antigen IgE; (iii) degranulation of mast cells containing surface-bound anti-antigen IgE; and/or (iv) development of allergic symptoms (e.g., histamine release). In general, IgE binding sites are defined for a particular antigen or antigen

fragment by exposing that antigen or fragment to serum from allergic individuals (preferably of the species to whom inventive compositions are to be administered). It will be recognized that different individuals may generate IgE that recognize different epitopes on the same antigen.

Thus, it is typically desirable to expose antigen or fragment to a representative pool of serum samples. For example, where it is desired that sites recognized by human IgE be identified in a given antigen or fragment, serum is preferably pooled from at least 5-10, preferably at least 15, individuals with demonstrated allergy to the antigen. Those of ordinary skill in the art will be well aware of useful pooling strategy in other contexts.

“Immunologic inducing agents”: The term “immunological inducing agents” is used herein as agents that prompt the expression of Th1 stimulating cytokines by T-cells and include factors such as, CD40, CD40 ligand, oligonucleotides containing CpG motifs, TNF, and microbial extracts such as preparations of *Staphylococcus aureus*, heat killed *Listeria*, and modified cholera toxin.

Immunostimulatory sequences are oligodeoxynucleotides of bacterial, viral or invertebrate origin that are taken-up by APCs and activate them to express certain membrane receptors (e.g., B7-1 and B7-2) and secrete various cytokines (e.g., IL-1, IL-6, IL-12, TNF). These oligodeoxynucleotides containing unmethylated CpG motifs cause brisk activation and when injected into animals in conjunction with antigen, appear to skew the immune response to a Th1-type response. See, for example, Yamamoto, et al., *Microbiol. Immunol.* 36, 983 (1992); Krieg, et al., *Nature* 374, 546-548 (1995); Pisetsky, *Immunity* 5, 303 (1996); and Zimmerman, et al., *J. Immunol.* 160, 3627-3630 (1998).

“Inducible promoter”: The term “inducible promoter”, as used herein, means a promoter site which is activated directly by the presence or absence of a chemical agent or indirectly by an environmental stimulus such as temperature changes. A promoter is the region of DNA at which the enzyme RNA polymerase binds and initiates the process of gene transcription.

“Mast cell”: As will be apparent from context, the term “mast cell” is often used herein to refer to one or more of mast cells, basophils, and other cells having IgE receptors, which when activated by crosslinking bound IgE molecules, releases histamines, vasodilators, and/or other mediators of allergic responses.

“Microorganisms”: “Microorganisms” as used herein are cells, bacteria, fungi, viruses, algae, and protozoa. Preferred microorganisms can be genetically manipulated to produce a desired polypeptide(s).

“Peptide”: According to the present invention, a “peptide” comprises a string of at least three amino acids linked together by peptide bonds. Inventive peptides preferably contain only natural amino acids, although non-natural amino acids (i.e., compounds that do not occur in nature but that can be incorporated into a polypeptide chain; see, for example, <http://www.cco.caltech.edu/~dadgrp/Unnatstruct.gif>, which displays structures of non-natural amino acids that have been successfully incorporated into functional ion channels) and/or amino acid analogs as are known in the art may alternatively be employed. Also, one or more of the amino acids in an inventive peptide may be modified, for example, by the addition of a chemical entity such as a carbohydrate group, a phosphate group, a farnesyl group, an isofarnesyl group, a fatty acid group, a linker for conjugation, functionalization, or other modification, etc.

A peptide or polypeptide is derived from a protein if the amino acid sequence of the peptide or polypeptide is found within the amino acid sequence of the protein. The sequences are preferably identical but may have a sequence homology between approximately 80-100%. It is also recognized that amino acid residues may be replaced with other amino acids residues with similar physical properties such as hydrophobicity, hydrophilicity, charge, aromatic structures and polarity.

“Reduced IgE binding”: An inventive composition or antigen is considered to have “reduced IgE binding” if it demonstrates a lower level of interaction with IgE when compared with unmodified antigen in any available assay. For example, a modified antigen is considered to have reduced IgE binding if (i) its affinity for anti-antigen IgE (assayed, for example, using direct binding studies or indirect competition studies) is reduced at least about 2-5 fold, preferably at least about 10, 20, 50, or 100 fold as compared with intact antigen; (ii) ability of the modified antigen to support cross-linking of anti-antigen IgE is reduced at least about 2-fold, preferably at least about 5, 10, 20, 50, or 100 fold as compared with intact antigen; (iii) mast cells containing surface-bound anti-antigen IgE degranulate less (at least about 2 fold, preferably at least about 3, 5, 10, 20, 50, or 100 fold less) when contacted with modified as compared with

unmodified antigen; and/or (iv) individuals contacted with modified antigen develop fewer (at least about 2 fold, preferably at least about 3, 5, 10, 20, 50, or 100 fold fewer) allergic symptoms, or developed symptoms are reduced in intensity when exposed to modified antigens as compared with unmodified antigens.

5 “Secretion signals”: A secretion signal is any amino acid sequence which when conjugated to a peptide, polypeptide or protein facilitates the transport of the conjugate fusion proteins across cell membranes. For uses of secretion signals in microorganisms, transport of fusion proteins involves crossing an inner membrane into the periplasm. It is preferred that secretion signals also facilitate transport of fusion proteins across an outer membrane into an
10 extracellular medium. Secretion of proteins into the extracellular medium is considered “excretion”.

“Sensitized mast cell”: A “sensitized” mast cell is a mast cell that has surface-bound antigen specific IgE molecules. The term is necessarily antigen specific. That is, at any given time, a particular mast cell will be “sensitized” to certain antigens (those that are recognized by
15 the IgE on its surface) but will not be sensitized to other antigens.

“Small molecules”: As used herein, the term “small molecule” refers to a compound either synthesized in the laboratory or found in nature. Typically, a small molecule is organic and is characterized in that it contains several carbon-carbon bonds, and has a molecular weight of less than 1500 daltons, although this characterization is not intended to be limiting for the
20 purposes of the present invention. Examples of “small molecules” that are allergens include without limitation penicillin, alcohols, and aspirin. Non-organic small molecule allergens include sulfites present in wine, for example.

“Susceptible individual”: According to the present invention, a person is susceptible to an allergic reaction if (i) that person has ever displayed symptoms of allergy after exposure to a
25 given antigen; (ii) members of that person’s genetic family have displayed symptoms of allergy against the allergen, particularly if the allergy is known to have a genetic component; and/or (iii) antigen-specific IgE are found in the individual, whether in serum or on mast cells.

“Th1 response” and “Th2 response”: Certain preferred peptides, polypeptides, proteins and compositions of the present invention are characterized by their ability to suppress a Th2

response and/or to stimulate a Th1 response preferentially as compared with their ability to stimulate a Th2 response. Th1 and Th2 responses are well-established alternative immune system responses that are characterized by the production of different collections of cytokines and/or cofactors. For example, Th1 responses are generally associated with production of cytokines such as IL-1 β , IL-2, IL-12, IL-18, IFN α , IFN γ , TNF β , etc; Th2 responses are generally associated with the production of cytokines such as IL-4, IL-5, IL-10, etc. The extent of T cell subset suppression or stimulation may be determined by any available means including, for example, intra-cytoplasmic cytokine determination. In preferred embodiments of the invention, Th2 suppression is assayed, for example, by quantitation of IL-4, IL-5, and/or IL-13 in stimulated T cell culture supernatant or assessment of T cell intra-cytoplasmic (e.g., by protein staining or analysis of mRNA) IL-4, IL-5, and/or IL-13; Th1 stimulation is assayed, for example, by quantitation of IFN α , IFN γ , IL-2, IL-12, and/or IL-18 in activated T cell culture supernatant or assessment of intra-cytoplasmic levels of these cytokines.

Description of Certain Preferred Embodiments

The present invention provides compositions and methods for modulating the immune response in a subject. It is an aspect of the present invention that undesirable allergic immune responses to antigens in a subject are treated or prevented by administering modified cells, virions, or spores ("microorganisms") that express allergens of interest. By using genetically modified microorganisms to express and deliver allergens, exposure of the allergens to the subject's IgE-mediated allergic immune response is reduced or eliminated. Without limitation to the mechanisms proposed, it is expected that the modified microorganisms of the present invention are engulfed by antigen-presenting cells (APCs) such as macrophages and dendritic cells without exposing allergens to IgE antibodies. Once inside the APCs, the expressed allergens are released by lysis of the microorganisms or secretion of the antigen by the microorganisms. The allergens are then processed, for example through partial digestion by the APCs, and displayed on the cell surface.

Once the processed antigens are displayed on the cell surface, activation of the cytotoxic T cell response and helper T cell response promotes cellular immune response and Th1-mediated

B cell response to protein allergens. In addition, the processed antigens have a reduced ability (or no ability) to bind and crosslink IgE antibodies located on the surface of mast cells and basophils leading to the release of histamines and other vasodilators responsible for allergic and sometimes fatal anaphylactic responses.

HOST MICROORGANISMS

Any microorganism capable of expressing (e.g., by expression of polypeptide or protein allergens, or by expression of polypeptide or protein enzymes involved in synthesis of small molecule allergens) allergens may be used as delivery vehicles in accordance with the present invention. Such microorganisms include but are not limited to bacteria, viruses, fungi (including yeast), algae, and protozoa. Generally, microorganisms are single cell, single spore or single virion organisms. Additionally, included within the scope of the present invention are cells from multi-cellular organisms which have been modified to produce a polypeptide of interest. Microorganisms that can be genetically manipulated to produce a desired polypeptide are preferred. (Ausubel et al. *Current Protocols in Molecular Biology*. Wiley and Sons, Inc. 1999, incorporated herein by reference) Genetic manipulation includes mutation of the host genome, insertion of genetic material into the host genome, deletion of genetic material of the host genome, transformation of the host with extrachromosomal genetic material, transformation with linear plasmids, transformation with circular plasmids, insertion of genetic material into the host (e.g., injection of mRNA), insertion of transposons, and chemical modification of genetic material. Methods for constructing nucleic acids (including an expressible gene), and introducing such nucleic acids into an expression system to express the encoded protein are well established in the art (see, for example, Sambrook et al., *Molecular Cloning: A Laboratory Manual*, 2nd Ed., Cold Spring Harbor Laboratory Press, Cold Spring Harbor, NY, 1989, incorporated herein by reference).

Use of microorganisms such as bacteria and yeast for allergen delivery in accordance with the present invention offers many advantages over delivery of allergens that are not encapsulated inside microorganisms for immunotherapy. Generally, microorganisms, such as bacteria, are known to act as an adjuvant (for a review, see for example, Freytag et al. *Curr Top*

Microbiol Immunol 236:215-36, 1999). Therefore, use of microorganisms to delivery allergens to subjects, and APCs of subjects, provides protection of the allergen from IgE-mediated allergic responses and also provides an adjuvant effect which elicits a Th1-type immune response from an individual susceptible to allergic responses. In addition, use of non-pathogenic, non-
5 infectious, attenuated and/or killed microorganisms reduces or eliminates toxicity which may be associated with allergen delivery vehicles.

In a preferred embodiment, bacteria are used as protein delivery microorganisms. Generally, bacteria are classified as gram-negative or gram-positive depending on the structure of the cell walls. Those skilled in the art are capable of identifying gram-negative and gram-
10 positive bacteria which may be used to express proteins in accordance with the present invention. Non-limiting examples of genera and species of gram-negative bacteria include *Escherichia coli*, *Vibrio cholera*, *Salmonella*, *Listeria*, *Legionella*, *Shigella*, *Yersenia*, *Citrobacter*, *Enterobacter*, *Klebsiella*, *Morganella*, *Proteus*, *Providencia*, *Serratia*, *Plesiomonas*, *Aeromonas*. Non-limiting examples of genera and species of gram-positive bacteria which may be used in the present
15 invention include *Bacillus subtilis*, *Sporolactobacillus*, *Clostridium*, *Arthrobacter*, *Micrococcus*, *Mycobacterium*, *Peptococcus*, *Peptostreptococcus*, and *Lactococcus*.

Gram-negative bacterial systems for use as delivery vehicles are known and may be used in the present invention. For example, *E. coli* is a well-studied bacteria, and methods of protein expression in *E. coli* are well-established. Most strains of *E. coli* have the advantage of being
20 non-pathogenic since *E. coli* is found naturally in the gut. Therefore, *E. coli* is preferred as a delivery vehicle in the present invention. In addition, Calderwood *et al.* (US Patent 5,747,028) utilize *Vibrio cholerae* as a delivery vehicle for production of antigens for use as a live vaccine against infectious organisms. Miller and Mekalanos (US Patent 5,731,196) utilize *Salmonella* as delivery vehicle for production of antigens for use as a live vaccine against infectious organisms.
25 Hess *et al.* (*Proc. Natl. Acad. Sci. USA* 93:1458-1463, 1996) utilize recombinant attenuated *Salmonella* which secretes antigenic determinants of *Listeria* as a live vaccine to protect against listeriosis. Donner *et al.* (WO 98/50067) utilize attenuated *Salmonella typhimurium* as a gram-negative host for secretion of polypeptides for controlling fertility and also teach that other

attenuated gram-negative strains including *Yersinia* may be used to express and secrete such polypeptides.

Gram-positive bacteria have also been studied as delivery vehicles for proteins to modulate an immune response in a subject. WO 97/14806 describes the use of *Lactococcus* to deliver polypeptides into a body to enhance the immune response to the polypeptides. However, WO 97/14806 does not teach the use of *Lactococcus* to treat patients with food allergies and venom allergies which may result in anaphylaxis

In another preferred embodiment, yeast are used as protein delivery microorganisms. It is well known that yeast are amenable to genetic manipulation to express a protein or proteins of choice (Ausubel et al. supra). Furthermore, in general most yeast are non-pathogenic. Without limitation to these species, two well-characterized species of yeast are the budding yeast *Saccharomyces cerevisiae*, and the fission yeast, *Schizosaccharomyces pombe*. Moreover, the administration of yeast that express protein antigens to alter an immune response has been studied. Duke et al. (US Patent No. 5,830,463; "Duke") describe the use of yeast to express proteins after administration of the yeast to a mammal. However, Duke does not teach the use of yeast to treat patients with food allergies and venom allergies which may result in anaphylaxis.

Microorganisms of the present invention may be administered to a subject as live or dead microorganisms. Preferably if the microorganisms are administered as live microorganisms, they are non-pathogenic or attenuated pathogenic microorganisms. For applications of the invention where live microorganisms are administered to individuals, preferably the microorganisms are attenuated and/or are administered in suitable encapsulation materials and/or as pharmaceutical compositions as vaccines to decrease an individuals immune response to the microorganism and/or allergenic compounds. Generally, attenuation involves genetically modifying the infectious pathogenic microorganism to reduce or eliminate the infectious ability of the microorganism. Preferably, the microorganism is attenuated such that an individual inoculated with the microorganism does not suffer any cytotoxic effects from the presence of the microorganism. Particularly preferred attenuated microorganisms are infectious intracellular pathogens which are phagocytosed by antigen-presenting cells in individuals who are exposed to

the microorganism. Examples of microorganisms which are intracellular pathogens include *Salmonella*, *Mycobacterium*, *Leishmania*, *Legionella*, *Listeria*, and *Shigella*.

Microorganisms of the present invention may be administered to subjects after killing the microorganisms. Any method of killing the microorganisms may be utilized that does not greatly alter the antigenicity of the expressed polypeptides. Methods of killing microorganism include but are not limited to using heat, antibiotics, chemicals such as iodine, bleach, ozone, and alcohols, radioactivity (i.e. irradiation), UV light, electricity, and pressure. Preferred methods of killing microorganisms are reproducible and kill at least 99% of the microorganisms. Particularly preferred is the use of heat above 50 degrees Celsius for a period of time that kills greater than 99% of the cells and preferably 100% of the cells.

INDUCIBLE SYSTEMS

In another preferred embodiment, the inventive expression of allergens by microorganisms is regulated so that synthesis occurs at a controlled time after the live microorganism is administered to an individual. Preferably the induction of protein synthesis is regulated so that activation occurs after the microorganism(s) is taken up by antigen-presenting cells (APCs) and phagocytosed into the endosome. A desirable result of this regulation is that production of the allergen of interest occurs inside the APCs and therefore reduces or eliminates the exposure of the allergen to IgE molecules bound to the surface of histamine-releasing mast cells and basophils. This reduces or eliminates the risk of anaphylaxis during administration of microorganisms that produce anaphylactic antigens.

Any method of controlling protein synthesis in the microorganism may be used in accordance with the present invention. Preferably, the method of controlling protein synthesis utilizes an inducible promoter operatively-linked to the gene of interest (e.g., a gene which encodes a signal peptide and protein antigen). Many systems for controlling transcription of a gene using an inducible promoter are known (Ausubel et al. *Current Protocols in Molecular Biology*. Wiley and Sons. New York. 1999). Generally, inducible systems either utilize activation of the gene or derepression of the gene. It is preferred that the present invention utilizes activation of a gene to induces transcription. However, inducible systems using

derepression of a gene may also be used in the present invention. Systems using activation are preferred because these systems are able to tightly control inactivation (and hence basal level synthesis) since derepression may result in low levels of transcription if the derepression is not tight.

5 Methods of inducing transcription include but are not limited to induction by the presence or absence of a chemical agent, induction using a nutrient starvation inducible promoter, induction using a phosphate starvation inducible promoter and induction using a temperature sensitive inducible promoter. A particularly preferred system for regulating gene expression utilizes tetracycline controllable expression system. Systems which utilize the tetracycline
10 controllable expression system are commercially available (see for example, Clontech, Palo Alto, CA).

 Another particularly preferred system for regulating gene expression utilizes an ecdysone-inducible expression system which is also commercially available (Invitrogen, Carlsbad CA). The ecdysone-inducible expression system is based on the ability of ecdysone
15 which is an insect hormone, to activate gene expression by binding to the ecdysone receptor. The expression system utilizes a modified heterologous protein containing the ecdysone receptor, a viral transactivation domain (from VP16) and the retinoid X receptor derived from mammalian cells to bind to a modified ecdysone response element in the presence of a ligand such as ecdysone or an analog (e.g. muristerone A, ponasterone A).

20 It is preferred that inducible systems for use in the present invention utilize inducing agents that are non-toxic to mammals cells including humans. Furthermore, it is preferred that transcriptional inducing agents permeate cells membranes. More specifically for activation of protein synthesis in microorganisms after phagocytosis by APCs, transcriptional inducing agents must be able to pass through cells membranes of the APC and cell membranes of the
25 microorganism to activate the expression of genes encoding protein allergens in accordance with the present invention. Since both tetracycline and ecdysone are able to pass through cell membranes and are non-toxic, tetracycline-inducible systems and ecdysone-inducible systems are ideally suited for use in the present invention. However, the use of inducible systems in the present invention is not limited to those systems.

It is also preferred that bacteria that have not been phagocytosed are killed before induction of genes expressing polypeptide allergens of interest. A preferred method of killing bacteria is to use antibiotics which are not permeable to mammalian cell membranes such that only bacteria that are not phagocytosed are killed. The use of antibiotics in accordance with the present embodiment reduces or eliminates the production of polypeptides by bacteria outside antigen presenting cells. It is important to reduce or eliminate exposure of allergen-producing bacteria to the immune system, especially bacteria that secrete polypeptides, which could elicit a potentially lethal anaphylactic reaction in an individual. Those having ordinary skill in the art are readily aware of antibiotics which may be used. Such antibiotics include but are not limited to penicillin, ampicillin, cephalosporin, griseofulvin, bacitracin, polymyxin b, amphotericin b, erythromycin, neomycin, streptomycin, tetracycline, vancomycin, gentamicin, and rifamycin

SECRETION SIGNALS

In another embodiment of the present invention, expressed allergens (and/or immunomodulatory molecules, such as cytokines; see below) are secreted by the microorganisms. Preferably, secretion of the allergens occurs inside a mammalian cell to reduce or eliminate exposure of allergens to a subject's allergic immune response. Secretion of polypeptides includes secretion into the extracellular medium and secretion of polypeptides into the periplasm of microorganisms such as gram-negative bacteria and yeast. Advantages of secreting allergens into the periplasm include reducing leakage of the allergens prior to phagocytosis of the microorganism. This advantage is most applicable in non-inducible systems. Advantages of secreting allergens into the extracellular medium in inducible systems include maximizing the amount of allergens available for processing by antigen-presenting cells after phagocytosis of the microorganisms of the present invention.

To express secreted polypeptides in bacteria, a variety of bacterial secretion signals known in the art may be used. For example, the Sec-dependent process in *E. coli* is one which is well known (for a review see Driessen et al. *Curr. Opin. Microbiology* 1:216-22). In addition, the OmpA signal peptide in *E. coli* has been described by Wong and Sutherland (US Patent 5,223,407). Fusion proteins containing either of these secretion signal peptides are not fully

secreted by the bacteria, but rather transported across the inner membrane of the gram-negative bacteria into the periplasm. These secretion signals may be used in the present invention to transport allergenic or immunomodulatory polypeptides into the periplasm of bacteria. After administration of the genetically engineered bacteria to an individual and subsequent phagocytosis by APCs, the allergenic or immunomodulatory polypeptides in the periplasm are released after degradation of the outer membrane by enzymes in the endosome of the APCs. Preferably, the bacteria synthesize and secrete the polypeptides into the periplasm and are killed, preferably heat-killed, before administration. However, it is recognized that attenuated bacteria may be used to secrete inventive allergens into the periplasm and administered to individuals.

In another preferred embodiment of secreted proteins or polypeptides, fusion proteins containing secretion signal sequences and allergenic or immunomodulatory sequences are fully secreted into the extracellular medium by a microorganism after synthesis of the protein. Such secretion signals include those found in hemolysin and listeriolysin. In a particularly preferred embodiment, the hemolysin complex of *E. coli* is used to transport allergenic or immunomodulatory polypeptides across the inner and outer membrane of a microorganism (e.g. *E. coli*, *Salmonella*, *Shigella*, *Vibrio*, *Yersinia*, *Citrobacter*, *Serratia*, *Pseudomonas*) into the extracellular medium (Spreng et al. *Mol. Microbiol.* 31:1589-1601, 1999, and references therein all of which are incorporated herein by reference). Fusion of HlyAs to proteins and polypeptides has been shown to result in secretion of these fusion proteins utilizing the hemolysin secretion system (Blight and Holland, *Trends Biotechnol.* 1994 Nov;12(11):450-5.; Gentshev et al., *Behring Inst Mitt.* 1994 Dec;(95):57-66)

The hemolysin protein (HlyA) contains a C-terminal transport signal (HlyAs) which is approximately 50-60 amino acids in length (Hess et al., *Mol Gen Genet.* 1990 Nov;224(2):201-8; Jarchau et al., *Mol Gen Genet.* 1994 Oct 17;245(1):53-60). The HlyA protein is secreted across the inner and outer cellular membranes by the hemolysin secretion system. This complex contains three membrane proteins. Two of these proteins, HlyB and HlyD, are located in the inner membrane, and the third TolC, is located at the outer membrane. Genes encoding these proteins are part of the hemolysin operon which consists of four genes *hlyC*, *hlyA*, *hlyB*, and

hlyD (Wagner et al., *J Bacteriol.* 1983 Apr;154(1):200-10; Gentschev. *Gene.* 1996 Nov 7;179(1):133-40).

In a preferred embodiment for use of the Hly secretion system, DNA plasmids (vectors) are used to express fusion proteins containing the HlyAs signal peptide and allergenic or immunomodulatory polypeptides. The genes encoding the transport complex (*hlyB*, and *hlyD*) are encoded by the same vector. It is recognized that multiple vectors can be used to encode and express these genes, or that sequences encoding these genes can be inserted into the host genome for expression. Preferably, a single vector contains the complete hemolysin operon including the *hly* specific promoter and an enhancer-type regulator *hlyR*; the HlyA gene where only the minimal polypeptide sequence necessary to transport a fusion protein is present; and the antigen of interest. TolC protein is generally produced by the host *E. coli* system. However, in systems where *tolC* DNA is not encoded by a host organism, *tolC* can be encoded by a vector.

In a particularly preferred embodiment, the secretion plasmid pMOhly1 described in WO 98/50067 ("Donner") is used to express fusion proteins containing secretion signal sequences and polypeptides related to inducing anaphylaxis in individuals. The secretion vector pMOhly1 contains the complete hemolysin operon including the *hly* specific promoter and an enhancer-type regulator *hlyR*. A majority of the *hlyA* gene has been deleted so that HlyA encodes only the 34 amino terminal and 61 carboxyl terminal amino acids (HlyA_s). A unique Nsi restriction enzyme site between the amino terminal and carboxyl terminal residues of HlyA facilitates the insertion of heterologous genes or gene fragments into the reading frame of HlyA_s. The genetic information for antigens the size of 10-1000 amino acids can be inserted into this secretion vector pMOhly1, which facilitates the secretion of these antigens in attenuated *Salmonella* and other gram-negative attenuated inoculation strains (e.g. *E. coli*, *Vibrio cholera*, *Yersina enterocolitica*). In contrast to other secretion systems, the secretion of fusion proteins using a single plasmid is described by Donner. An advantage of the hemolysin secretion system in comparison to conventional transport systems is the larger size of the fusion proteins synthesized and secreted according to the methods taught in Donner. Conventional secretion systems for the presentation of antigens are only capable of secreting relatively short peptides to the outer part of the bacterial cell (Cardenas and Clements, *Clin Microbiol Rev.* 1992 Jul;5(3):328-42).

ANTIGENS AND ALLERGENS

In general, any allergen may be produced by microorganisms in accordance with the present invention. Preferred allergens are found in certain foods, venom, drugs or rubber and are capable of eliciting allergic responses, and in particular anaphylactic allergic responses in an individual. Particularly preferred allergens are protein or polypeptide allergens.

In a preferred embodiment, microorganisms of the present invention produce allergenic proteins that elicit allergies, possibly anaphylaxis, and are found in foods, venoms, drugs, and rubber-based products. Particularly preferred allergenic proteins that induce anaphylaxis, such as several protein allergens found in food (peanut, milk, egg, wheat), insect venom (i.e. bees, reptiles), drugs, and latex. Non-limiting examples of protein allergens found in food include proteins found in nuts (e.g., peanut walnut, almond, pecan, cashew, hazelnut, pistachio, pine nut, brazil nut), seafood (e.g. shrimp, crab, lobster, clams), fruit (e.g. plums, peaches, nectarines; *Ann Allergy Asthma Immunol* 7(6):504-8 (1996); cherries, *Allergy* 51(10):756-7 (1996)), seeds (sesame, poppy, mustard), and soy and dairy products (e.g., egg, milk).

Some protein allergens found in nuts are related to legume allergies and may be used instead of the legume proteins (e.g. peanuts, soybeans, lentils; *Ann Allergy Asthma Immunol* 77(6): 480-2 (1996). Also, protein antigens found in pollen-related food allergies may be used (e.g. birch pollen related to apple allergies). Other protein allergens found in foods include those found in young garlic (*Allergy* 54(6):626-9 (1999), and for children allergic to house dust mites, allergens found in snails (*Arch Pediatr* 4(8):767-9 (1997)). Protein allergens in wheat are known to cause exercise-induced allergies (*J Allergy Clin Immunol* 1999 May;103(5 Pt 1):912-7).

Stings from organisms that inject venoms, such as insect stings are known to cause anaphylaxis in individuals with allergies to the venom. In general, insect venom includes venom from Hymenoptera such as bees, hornets, wasps, yellow jackets, velvet ants, and fire ants. In particular for example, venom from honey bees of the genus *Apis* can cause anaphylaxis in stung victims who are allergic (Weber et al. *Allergy* 42:464-470). The venom from honey bees contains numerous compounds which have been extensively studied and characterized (see for a reference, Banks and Shipolini. *Chemistry and Pharmacology of Honey-bee Venom*. Chapter 7 of

Venoms of the Hymenoptera. Ed. T. Pick. Academic Press. London. 1986). The two main components of bee venom are phospholipase A2 and melittin and are preferred protein allergens for use in the present invention for treating and preventing allergies to bee venom.

In certain uses of the present invention, it will be desirable to work in systems in which a single compound (e.g., a single protein) is responsible for most observed allergy. In other cases, the invention can be applied to more complex allergens. Therefore, collections of more than one antigen can be used so that immune responses to multiple antigens may be modulated simultaneously.

Appendix A presents a representative list of certain known protein antigens. As indicated, the amino acid sequence is known for many or all of these proteins, either through knowledge of the sequence of their cognate genes or through direct knowledge of protein sequence, or both. Of particular interest are anaphylactic antigens.

In another embodiment of allergenic antigens, microorganisms are genetically engineered to synthesize and secrete modified allergenic polypeptides that elicit anaphylaxis when exposed to individuals who are susceptible to anaphylactic shock. Preferably, the allergens are modified such that the ability to elicit anaphylaxis is reduced or eliminated. As previously discussed allergens elicit allergic responses which are sometimes severe enough to induce anaphylactic shock by crosslinking IgE antibodies bound to the surface of mast cells and basophils. The IgE crosslinking releases compounds such as histamines which causes symptoms related to allergies and anaphylactic shock. In accordance with the present invention, microorganisms are used to synthesize and secrete antigens which are modified to reduce or eliminate IgE binding sites while still maintaining antigenicity or immunomodulatory activity (U.S.S.N. 09/141,220 incorporated herein by reference). This reduces the risk of allergic or anaphylactic responses in individuals treated with vaccines containing these engineered microorganisms.

The amount of antigen to be employed in any particular composition or application will depend on the nature of the particular antigen and of the application for which it is being used, as will readily be appreciated by those of ordinary skill in the art. The experiments described in Examples 1-4 suggest that larger amounts of polypeptides are useful for inducing Th1 responses. The amount of antigen can be controlled by a variety of factors including but not limited to

expression systems, inducible expression systems, levels of secretion and excretion, methods of killing bacteria before delivery. Those of ordinary skill in the art are capable of determining the desired levels of antigens to be produced by bacteria and delivered to individuals.

It is recognized that multiple antigenic molecules may be delivered by bacteria simultaneously in accordance with the methods of the present invention. Without limitation, different antigenic determinants for one antigenic protein may be delivered. Different antigenic determinants from different antigenic proteins may also be delivered. Further, multiple antigenic polypeptides and proteins may be delivered in accordance with the present invention. It is also recognized that single or multiple antigenic polypeptides and single or multiple cytokines may be delivered to individuals by bacteria in accordance with the present invention. For example but without limitation, allergenic antigens of the present invention and immunomodulatory molecules such as interleukins may be delivered by bacteria using secreted or non-secreted methods in accordance with the present invention.

DIAGNOSTIC AND THERAPEUTIC REAGENTS

The first step in making the modified allergen is to identify IgE binding sites and/or immunodominant IgE binding sites. The second step is to mutate one or more of the IgE binding sites, preferably including at a minimum one of the immunodominant sites, or to react the allergen with a compound that selectively blocks binding to one or more of the IgE binding sites. The third step is to make sufficient amounts of the modified allergen for administration to persons or animals in need of tolerance to the allergen, where the modified allergen is administered in a dosage and for a time to induce tolerance, or for diagnostic purposes. The modified allergen can be administered by injection, or in some cases, by ingestion or inhalation.

A. Allergens.

Many allergens are known that elicit allergic responses, which may range in severity from mildly irritating to life-threatening. Food allergies are mediated through the interaction of IgE to specific proteins contained within the food. Examples of common food allergens include proteins from peanuts, milk, grains such as wheat and barley, soybeans, eggs, fish, crustaceans, and mollusks. These account for greater than 90% of the food allergies (Taylor, Food Techn. 39,

146-152 (1992). The IgE binding epitopes from the major allergens of cow milk (Ball, et al. (1994) *Clin. Exp. Allergy*, 24, 758-764), egg (Cooke, S.K. and Sampson, H.R. (1997) *J. Immunol.*, 159, 2026-2032), codfish (Aas, K., and Elsayed, S. (1975) *Dev. Biol. Stand.* 29, 90-98), hazel nut (Elsayed, et al. (1989) *Int. Arch. Allergy Appl. Immunol.* 89, 410-415), peanut (Burks et al., (1997) *Eur. J. Biochemistry*, 245:334-339; Stanley et al., (1997) *Archives of Biochemistry and Biophysics*, 342:244-253), soybean (Herein, et al. (1990) *Int. Arch. Allergy Appl. Immunol.* 92, 193-198) and shrimp (Shanty, et al. (1993) *J. Immunol.* 151, 5354-5363) have all been elucidated, as have others. Other allergens include proteins from insects such as flea, tick, mite, fire ant, cockroach, and bee as well as molds, dust, grasses, trees, weeds, and proteins from mammals including horses, dogs, cats, etc.

The majority of allergens discussed above elicit a reaction when ingested, inhaled, or injected. Allergens can also elicit a reaction based solely on contact with the skin. Latex is a well known example. Latex products are manufactured from a milky fluid derived from the rubber tree, *Hevea brasiliensis* and other processing chemicals. A number of the proteins in latex can cause a range of allergic reactions. Many products contain latex, such as medical supplies and personal protective equipment. Three types of reactions can occur in persons sensitive to latex: irritant contact dermatitis, and immediate systemic hypersensitivity. Additionally, the proteins responsible for the allergic reactions can fasten to the powder of latex gloves. This powder can be inhaled, causing exposure through the lungs. Proteins found in latex that interact with IgE antibodies were characterized by two-dimensional electrophoresis. Protein fractions of 56, 45, 30, 20, -14, and less than 6.5 kd were detected (Posch A. et al., (1997) *J. Allergy Clin. Immunol.* 99(3), 385-395). Acidic proteins in the 8-14 kd and 22 -24 kd range that reacted with IgE antibodies were also identified (Posch A. et al., (1997) *J. Allergy Clin. Immunol.* 99(3), 385-395. The proteins prohevein and hevein, from hevea brasiliensis, are known to be major latex allergens and to interact with IgE (Alenius, H., et al., *Clin. Exp. Allergy* 25(7), 659-665; Chen Z., et al., (1997) *J. Allergy Clin. Immunol.* 99(3), 402-409). Most of the IgE binding domains have been shown to be in the hevein domain rather than the domain specific for prohevein (Chen Z., et al., (1997) *J. Allergy Clin. Immunol.* 99(3), 402-409). The main IgE-binding epitope of prohevein is thought to be in the N-terminal, 43 amino acid

fragment (Alenius H., et al., (1996) *J. Immunol.* 156(4), 1618-1625). The hevein lectin family of proteins has been shown to have homology with potato lectin and snake venom disintegrins (platelet aggregation inhibitors) (Kielisqewski, M.L., et al., (1994) *Plant J.* 5(6), 849-861).

B. Identification of IgE Binding Sites.

5 Allergens typically have both IgE and IgG binding sites and are recognized by T cells. The binding sites can be determined either by using phage display libraries to identify conformational epitopes (Eichler and Houghten, (1995) *Molecular Medicine Today* 1, 174-180; Jensen-Jarolim et al., (1997) *J. Appl. Clin. Immunol.* 101, 5153a) or by using defined peptides derived from the known amino acid sequence of an allergen (see examples below), or by binding
10 of whole protein or protein fragments to antibodies, typically antibodies obtained from a pooled patient population known to be allergic to the allergen. It is desirable to modify allergens to diminish binding to IgE while retaining their ability to activate T cells and in some embodiments by not significantly altering or decreasing IgG binding capacity. This requires modification of one or more IgE binding sites in the allergen.

15 A preferred modified allergen is one that can be used with a majority of patients having a particular allergy. Use of pooled sera from allergic patients allows determination of one or more immunodominant epitopes in the allergen. Once some or all of the IgE binding sites are known, it is possible to modify the gene encoding the allergen, using site directed mutagenesis by any of a number of techniques, to produce a modified allergen as described below, and thereby express
20 modified allergens. It is also possible to react the allergen with a compound that achieves the same result as the selective mutation, by making the IgE binding sites inaccessible, but not preventing the modified allergen from activating T cells, and, in some embodiments, by not significantly altering or decreasing IgG binding.

Assays to assess an immunologic change after the administration of the modified allergen are
25 known to those skilled in the art. Conventional assays include RAST (Sampson and Albergo, 1984), ELISAs (Burks, et al. 1986) immunoblotting (Burks, et al. 1988), and *in vivo* skin tests (Sampson and Albergo 1984). Objective clinical symptoms can be monitored before and after the administration of the modified allergen to determine any change in the clinical symptoms.

It may be of value to identify IgEs which interact with conformational rather than linear epitopes. Due to the complexity and heterogeneity of patient serum, it may be difficult to employ a standard immobilized allergen affinity-based approach to directly isolate these IgEs in quantities sufficient to permit their characterization. These problems can be avoided by isolating some or all of the IgEs which interact with conformational epitopes from a combinatorial IgE phage display library.

Steinberger et al. (Steinberger, P., Kraft D. and Valenta R. (1996) "Construction of a combinatorial IgE library from an allergic patient: Isolation and characterization of human IgE Fabs with specificity for the major Timothy Grass pollen antigen," *Phl p. 5 J. Biol. Chem.* 271, 10967-10972) prepared a combinatorial IgE phage display library from mRNA isolated from the peripheral blood mononuclear cells of a grass allergic patient. Allergen-specific IgEs were selected by panning filamentous phage expressing IgE Fabs on their surfaces against allergen immobilized on the wells of 96 well microtiter plates. The cDNAs were then isolated from allergen-binding phage and transformed into E coli for the production of large quantities of monoclonal, recombinant, allergen-specific IgE Fabs.

If native allergen or full length recombinant allergen is used in the panning step to isolate phage, then Fabs corresponding to IgEs specific for conformational epitopes should be included among the allergen-specific clones identified. By screening the individual recombinant IgE Fabs against denatured antigen or against the relevant linear epitopes identified for a given antigen, the subset of conformation-specific clones which do not bind to linear epitopes can be defined.

To determine whether the library screening has yielded a complete inventory of the allergen-specific IgEs present in patient serum, an immunocompetition assay can be performed. Pooled recombinant Fabs would be preincubated with immobilized allergen. After washing to remove unbound Fab, the immobilized allergen would then be incubated with patient serum. After washing to remove unbound serum proteins, an incubation with a reporter-coupled secondary antibody specific for IgE Fc domain would be performed. Detection of bound reporter would allow quantitation of the extent to which serum IgE was prevented from binding to allergen by recombinant Fab. Maximal, uncompeteted serum IgE binding would be determined using allergen which had not been preincubated with Fab or had been incubated with nonsense

Fab. If IgE binding persists in the face of competition from the complete set of allergen-specific IgE Fab clones, this experiment can be repeated using denatured antigen to determine whether the epitopes not represented among the cloned Fabs are linear or conformational.

Production of Recombinant or Modified Allergens

A modified allergen will typically be made using recombinant techniques. Expression in a procaryotic or eucaryotic host including bacteria, yeast, and baculovirus-insect cell systems are typically used to produce large (mg) quantities of the modified allergen. It is also possible to make the allergen synthetically, if the allergen is not too large, for example, less than about 25-40 amino acids in length.

ADJUVANTS AND IMMUNOSTIMULATORY AGENTS

Compositions and methods of the present invention include the use of adjuvants and immunomodulatory polypeptides or immunostimulatory factors to modulate an individual's immune response. Immunologic adjuvants are agents that enhance specific immune responses to vaccines. Formulation of vaccines with potent adjuvants is desirable for improving the performance of vaccines composed of antigens. Adjuvants may have diverse mechanisms of action and should be selected for use based on the route of administration and the type of immune response (antibody, cell-mediated, or mucosal immunity) that is desired for a particular vaccine

In general, immunomodulatory polypeptides include cytokines which are small proteins or biological factors (in the range of 5-20 kD) that are released by cells and have specific effects on cell-cell interaction, communication and behavior of other cells. As previously described, cytokines in accordance with the present invention are proteins that are secreted to T-cells to induce a Th1 or Th2 response. Preferably, the cytokine(s) to be administered is/are selected to reduce production of a Th2 response to antigens associated with anaphylaxis. One preferred method of reducing a Th2 response is through induction of the alternative response. Cytokines that, when expressed during antigen delivery into cells, induce a Th1 response in T cells (i.e., "Th1 stimulating cytokines") include IL-12, IL-2, I-18, IL-1 or fragments thereof, IFN γ , and/or

Other compounds that are immunomodulatory include immunological inducing agents. These inducing agents prompt the expression of Th1 stimulating cytokines by T-cells and include factors such as, CD40, CD40 ligand, oligonucleotides containing CpG motifs, TNF, and microbial extracts such as preparations of *Staphylococcus aureus*, heat killed *Listeria*, and modified cholera toxin, etc.

Those of ordinary skill in the art readily appreciate the preferred types of adjuvants for use with particular antigen compositions. In general, immunologic adjuvant include gel-type adjuvants (e.g. aluminum hydroxide/aluminum phosphate, calcium phosphate), microbial adjuvants (e.g. DNA such as CpG motifs; endotoxin such as monophosphoryl lipid A; exotoxins such as cholera toxin, *E. coli* heat labile toxin, and pertussis toxin; and muramyl dipeptide), oil-emulsion and emulsifier-based adjuvants (e.g. Freund's Incomplete Adjuvant, MF59, and SAF), particulate adjuvants (e.g. liposomes, biodegradable microspheres, and saponins), and synthetic adjuvants (e.g. nonionic block copolymers, muramyl peptide analogues, polyphosphazene, and synthetic polynucleotides).

Adjuvants that are known to stimulate Th2 responses are preferably avoided. Particularly preferred adjuvants include, for example, preparations (including heat-killed samples, extracts, partially purified isolates, or any other preparation of a microorganism or macroorganism component sufficient to display adjuvant activity) of microorganisms such as *Listeria monocytogenes* or others (e.g., Bacille Calmette-Guerin [BCG], *Corynebacterium* species, *Mycobacterium* species, *Rhodococcus* species, *Eubacteria* species, *Bordetella* species, and *Nocardia* species), and preparations of nucleic acids that include unmethylated CpG motifs (see, for example, U.S. Patent No. 5,830,877; and published PCT applications WO 96/02555, WO 98/18810, WO 98/16247, and WO 98/40100, each of which is incorporated herein by reference). Other preferred adjuvants reported to induce Th1-type responses and not Th2-type responses include, for example, Aviridine (N,N-di-octadecyl-N'-N'-bis (2-hydroxyethyl) propanediamine) and CRL 1005. Particularly preferred are ones that induce IL-12 production, including microbial extracts such as fixed *Staphylococcus aureus*, *Streptococcal* preparations, *Mycobacterium tuberculosis*, lipopolysaccharide (LPS), monophosphoryl lipid A (MPLA) from gram negative bacterial lipopolysaccharides (Richards et al. *Infect Immun* 1998 Jun;66(6):2859-65), *listeria*

monocytogenes, *toxoplasma gondii*, *leishmania major*. Some polymers are also adjuvants. For example, polyphosphazenes are described in U.S. Patent No. 5,500,161 to Andriavnov, et al. These can be used not only to encapsulate the microorganisms but also to enhance the immune response to the antigen.

5 If adjuvants are not synthesized by microorganisms in accordance with the present invention, adjuvants which are cytokines may be provided as impure preparations (e.g., isolates of cells expressing a cytokine gene, either endogenous or exogenous to the cell), but are preferably provided in purified form. Purified preparations are preferably at least about 90% pure, more preferably at least about 95% pure, and most preferably at least about 99% pure.

10 Alternatively, genes encoding the cytokines or immunological inducing agents may be provided, so that gene expression results in cytokine or immunological inducing agent production either in the individual being treated or in another expression system (e.g., an *in vitro* transcription/translation system or a host cell) from which expressed cytokine or immunological inducing agent can be obtained for administration to the individual. It is recognized that
15 microorganisms utilized to synthesize and deliver allergenic and/or immunomodulatory proteins according to the present invention can act as an adjuvant, and that preferred microorganisms are immunostimulatory adjuvants.

It will be appreciated by those of ordinary skill in the art that the inventive administration of microorganisms expressing cytokines and/or allergens may optionally be combined with the
20 administration of any other desired immune system modulatory factor such as, for example, an adjuvant or other immunomodulatory compound.

METHODS OF ADMINISTRATION

25 Formulations can be delivered to a patient by any available route including for example enteral, parenteral, topical (including nasal, pulmonary or other mucosal route), oral or local administration. The compositions are preferably administered in an amount effective to elicit cellular immunity and production of Th1-related IgG while minimizing IgE mediated responses. Also preferred are compositions administered in an effective amount to active T-cell response,

preferably Th1-type responses. For compositions of the present invention containing bacteria, administration is preferably delivered parenterally.

It is important to administer the modified allergen to an individual (human or animal) to decrease the clinical symptoms of allergic disease by using a method, dosage, and carrier which are effective. Allergen will typically be administered in an appropriate carrier, such as saline or a phosphate saline buffer. Allergen can be administered by injection subcutaneously, intramuscularly, or intraperitoneally (most humans would be treated by subcutaneous injection), by aerosol, inhaled powder, or by ingestion.

PHARMACEUTICAL COMPOSITIONS

Pharmaceutical compositions for use in accordance with the present invention may include a pharmaceutically acceptable excipient or carrier. As used herein, the term “pharmaceutically acceptable carrier” means a non-toxic, inert solid, semi-solid or liquid filler, diluent, encapsulating material or formulation auxiliary of any type. Some examples of materials which can serve as pharmaceutically acceptable carriers are sugars such as lactose, glucose, and sucrose; starches such as corn starch and potato starch; cellulose and its derivatives such as sodium carboxymethyl cellulose, ethyl cellulose and cellulose acetate; powdered tragacanth; malt; gelatin; talc; excipients such as cocoa butter and suppository waxes; oils such as peanut oil, cottonseed oil; safflower oil; sesame oil; olive oil; corn oil and soybean oil; glycols; such as propylene glycol; esters such as ethyl oleate and ethyl laurate; agar; buffering agents such as magnesium hydroxide and aluminum hydroxide; alginic acid; pyrogen-free water; isotonic saline; Ringer's solution; ethyl alcohol, and phosphate buffer solutions, as well as other non-toxic compatible lubricants such as sodium lauryl sulfate and magnesium stearate, as well as coloring agents, releasing agents, coating agents, sweetening, flavoring and perfuming agents, preservatives and antioxidants can also be present in the composition, according to the judgment of the formulator. The pharmaceutical compositions of this invention can be administered to humans and/or to other animals, orally, rectally, parenterally, intracisternally, intravaginally, intraperitoneally, topically (as by powders, ointments, or drops), buccally, or as an oral or nasal spray.

Liquid dosage forms for oral administration include pharmaceutically acceptable emulsions, microemulsions, solutions, suspensions, syrups and elixirs. In addition to the active compounds, the liquid dosage forms may contain inert diluents commonly used in the art such as, for example, water or other solvents, solubilizing agents and emulsifiers such as ethyl alcohol, isopropyl alcohol, ethyl carbonate, ethyl acetate, benzyl alcohol, benzyl benzoate, propylene glycol, 1,3-butylene glycol, dimethylformamide, oils (in particular, cottonseed, groundnut, corn, germ, olive, castor, and sesame oils), glycerol, tetrahydrofurfuryl alcohol, polyethylene glycols and fatty acid esters of sorbitan, and mixtures thereof. Besides inert diluents, the oral compositions can also include agents such as wetting agents, emulsifying and suspending agents, sweetening, flavoring, and perfuming agents.

Injectable preparations, for example, sterile injectable aqueous or oleaginous suspensions may be formulated according to the known art using suitable dispersing or wetting agents and suspending agents. The sterile injectable preparation may also be a sterile injectable solution, suspension or emulsion in a nontoxic parenterally acceptable diluent or solvent, for example, as a solution in 1,3-butanediol. Among the acceptable vehicles and solvents that may be employed are water, Ringer's solution, U.S.P. and isotonic sodium chloride solution. In addition, sterile, fixed oils are conventionally employed as a solvent or suspending medium. For this purpose any bland fixed oil can be employed including synthetic mono- or diglycerides. In addition, fatty acids such as oleic acid are used in the preparation of injectables.

In order to prolong the effect of an agent, it is often desirable to slow the absorption of the drug from subcutaneous or intramuscular injection. This may be accomplished by the use of a liquid suspension of crystalline or amorphous material with poor water solubility. The rate of absorption of the agent then depends upon its rate of dissolution which, in turn, may depend upon crystal size and crystalline form. Alternatively, delayed absorption of a parenterally administered drug form is accomplished by dissolving or suspending the drug in an oil vehicle. Injectable depot forms are made by forming microencapsule matrices of the drug in biodegradable polymers such as polylactide-polyglycolide. Depending upon the ratio of agent to polymer and the nature of the particular polymer employed, the rate of release of the agent can be controlled. Examples of other biodegradable polymers include poly(orthoesters) and

poly(anhydrides) Depot injectable formulations are also prepared by entrapping the drug in liposomes or microemulsions which are compatible with body tissues.

Compositions for rectal or vaginal administration are preferably suppositories which can be prepared by mixing the compounds of this invention with suitable non-irritating excipients or carriers such as cocoa butter, polyethylene glycol or a suppository wax which are solid at ambient temperature but liquid at body temperature and therefore melt in the rectum or vaginal cavity and release the active compound.

Solid dosage forms for oral administration include capsules, tablets, pills, powders, and granules. In such solid dosage forms, the active compound is mixed with at least one inert, pharmaceutically acceptable excipient or carrier such as sodium citrate or dicalcium phosphate and/or a) fillers or extenders such as starches, lactose, sucrose, glucose, mannitol, and silicic acid, b) binders such as, for example, carboxymethylcellulose, alginates, gelatin, polyvinylpyrrolidone, sucrose, and acacia, c) humectants such as glycerol, d) disintegrating agents such as agar-agar, calcium carbonate, potato or tapioca starch, alginic acid, certain silicates, and sodium carbonate, e) solution retarding agents such as paraffin, f) absorption accelerators such as quaternary ammonium compounds, g) wetting agents such as, for example, cetyl alcohol and glycerol monostearate, h) absorbents such as kaolin and bentonite clay, and i) lubricants such as talc, calcium stearate, magnesium stearate, solid polyethylene glycols, sodium lauryl sulfate, and mixtures thereof. In the case of capsules, tablets and pills, the dosage form may also comprise buffering agents.

Solid compositions of a similar type may also be employed as fillers in soft and hard-filled gelatin capsules using such excipients as lactose or milk sugar as well as high molecular weight polyethylene glycols and the like.

The solid dosage forms of tablets, dragees, capsules, pills, and granules can be prepared with coatings and shells such as enteric coatings and other coatings well known in the pharmaceutical formulating art. They may optionally contain opacifying agents and can also be of a composition that they release the active ingredient(s) only, or preferentially, in a certain part of the intestinal tract, optionally, in a delayed manner. Examples of embedding compositions which can be used include polymeric substances and waxes.

Solid compositions of a similar type may also be employed as fillers in soft and hard-filled gelatin capsules using such excipients as lactose or milk sugar as well as high molecular weight polyethylene glycols and the like.

5 The compounds can also be in micro-encapsulated form with one or more excipients as noted above. The solid dosage forms of tablets, dragees, capsules, pills and granules can be prepared with coatings and shells such as enteric coatings, release controlling coatings and other coatings well known in the pharmaceutical formulating art. In such solid dosage forms the active compound may be admixed with at least one inert diluent such as sucrose, lactose or starch. Such dosage forms may also comprise, as is normal practice, additional substances other than
10 inert diluents, e.g., tableting lubricants and other tableting aids such as magnesium stearate and microcrystalline cellulose. In the case of capsules, tablets and pills, the dosage forms may also comprise buffering agents. They may optionally contain opacifying agents and can also be of a composition that they release the active ingredient(s) only, or preferentially, in a certain part of the intestinal tract, optionally, in a delayed manner. Examples of embedding compositions
15 which can be used include polymeric substances and waxes.

Dosage forms for topical or transdermal administration of an inventive pharmaceutical composition include ointments, pastes, creams, lotions, gels, powders, solutions, sprays, inhalants or patches. The active component is admixed under sterile conditions with a pharmaceutically acceptable carrier and any needed preservatives or buffers as may be required.
20 Ophthalmic formulation, ear drops, eye drops are also contemplated as being within the scope of this invention.

The ointments, pastes, creams and gels may contain, in addition to an active compound of this invention, excipients such as animal and vegetable fats, oils, waxes, paraffins, starch, tragacanth, cellulose derivatives, polyethylene glycols, silicones, bentonites, silicic acid, talc and
25 zinc oxide, or mixtures thereof.

Powders and sprays can contain, in addition to the compounds of this invention, excipients such as lactose, talc, silicic acid, aluminum hydroxide, calcium silicates and polyamide powder, or mixtures of these substances. Sprays can additionally contain customary propellants such as chlorofluorohydrocarbons.

Transdermal patches have the added advantage of providing controlled delivery of a compound to the body. Such dosage forms can be made by dissolving or dispensing the compound in the proper medium. Absorption enhancers can also be used to increase the flux of the compound across the skin. The rate can be controlled by either providing a rate controlling membrane or by dispersing the compound in a polymer matrix or gel.

ENCAPSULATION

In a preferred embodiment, inventive compositions comprising live microorganisms are provided in association with an encapsulation device (see, for example, U.S.S.N. 60/169,330 entitled "Controlled Delivery of Antigens" filed Dec. 6, 1999, incorporated by reference herewith). Preferred encapsulation devices are biocompatible, are stable inside the body so that microorganisms are not released until after the encapsulation device reaches its intended destination (e.g. mucosal lining of the gut, endocytosis by antigen-presenting cells (APC)). For example, preferred systems of encapsulation are stable at physiological pH and degrade at acidic pH levels comparable to those found in the digestive tract or endosomes of APCs. Particularly preferred encapsulation compositions include but are not limited to ones containing liposomes, polylactide-co-glycolide (PLGA), chitosan, synthetic biodegradable polymers, environmentally responsive hydrogels, and gelatin PLGA nanoparticles. Inventive compositions may be encapsulated in combination with one or more adjuvants, targeting entities, or other agents including, for example, pharmaceutical carriers, diluents, excipients, oils, etc. Alternatively or additionally the encapsulation device itself may be associated with a targeting entity and/or an adjuvant.

Methods of encapsulating live cells are known and may also be used in accordance with the present invention for delivering antigen-secreting microorganisms to individuals. The following references are provided as examples of encapsulation of live cells. However, any method of encapsulating live cells may be used in the present invention. US Patent 5,084,350; US Patent 4,680,174; and US Patent 4,352,883 (all of which are incorporated herein by reference) describe the encapsulation of a prokaryotic or eukaryotic cell or cell culture in microcapsules. Briefly, US Patent 5,084,350; 4,680,174; and 4,352,883 disclose that a tissue

sample, cell, or cell culture to be encapsulated is first prepared in finely divided form in accordance with well-known techniques and suspended in an aqueous medium suitable for maintenance and for supporting the ongoing metabolic processes of the particular cells involved. Media suitable for this purpose generally are available commercially. Thereafter, a water-soluble substance which is physiologically compatible with the cells and which can be rendered water-insoluble to form a shape-retaining coherent spheroidal mass or other shape is added to the medium. The solution is then formed into droplets containing cells together with their maintenance or growth medium and is immediately rendered water-insoluble and gelled to form shape-retaining, typically spheroidal coherent masses.

The material used to induce gelation of the culture medium may be any non-toxic water-soluble material which, by a change in the surrounding temperature, pH, ionic environment, or concentration, can be converted to shape-retaining masses. Preferably, the material also is one which comprises plural, easily ionized groups, e.g., carboxyl or amino groups, which can react by salt formation with polymers containing plural groups which ionize to form species of the opposite charge. Use of this type of material enables the deposition of a membrane of a selected porosity range without damage to the labile cells. The presently preferred materials for forming the gelled masses are water-soluble natural or synthetic polysaccharides. Many such commercially available materials are typically extracted from vegetable matter and are often used as additives in various foods. Sodium alginate is the presently preferred water-soluble polysaccharide. Other usable materials include acidic fractions of guar gum, gum arabic, carrageenan, pectin, tragacanth gum or xanthan gums. These materials may be gelled when multivalent ions are exchanged for the acidic hydrogen or alkali metal ion normally associated with the carboxyl groups.

USES

The compositions of the present invention may be employed to treat or prevent allergic reactions in a subject. Subjects are animal and human patients in need of treatment for allergies. Preferably, the animal is a domesticated mammal (e.g., a dog, a cat, a horse, a sheep, a pig, a goat, a cow, etc). Animals also include laboratory animals such as mice, rats, hamsters,

monkeys, and rabbits. Any individual who suffers from allergy, or who is susceptible to allergy, may be treated. It will be appreciated that an individual can be considered susceptible to allergy without having suffered an allergic reaction to the particular antigen in question. For example, if the individual has suffered an allergic reaction to a related antigen (e.g., one from the same source or one for which shared allergies are common), that individual will be considered susceptible to allergy to the relevant antigen. Similarly, if members of an individual's family are allergic to a particular antigen, the individual may be considered to be susceptible to allergy to that antigen. More preferably, any individual who is susceptible to anaphylactic shock upon exposure to food allergens, venom allergens or rubber allergens may be treated according to the present invention.

The compositions of the present invention may be formulated for delivery by any route. Preferably, the compositions are formulated for injection, ingestion, or inhalation.

Therapy or desensitization with the modified allergens can be used in combination with other therapies, such as allergen-non-specific anti-IgE antibodies to deplete the patient of allergen-specific IgE antibodies (Boulet, et al. (1997) 155:1835-1840; Fahy, et al. (1997) *American J Respir. Crit. Care Med.* 155:1828-1834; Demoly, P. and Bousquet (1997) *J Am J Resp. Crit. Care Med.* 155:1825-1827), or by the pan specific anti-allergy therapy described in U. S. Serial No. 08/090,375 filed June 4, 1998, by M. Caplan and H. Sosin. Therapy with the modified allergen can also be administered in combination with an adjuvant such as IL-12, IL-16, IL-18, IFN γ .

The nucleotide molecule encoding the modified allergen can also be administered directly to the patient, for example, in a suitable expression vector such as a plasmid, which is injected directly into the muscle or dermis, or through administration of genetically engineered cells.

In general, effective dosages will be in the picogram to milligram range, more typically microgram to milligram. Treatment will typically be between twice/weekly and once a month, continuing for up to three to five years, although this is highly dependent on the individual patient response.

The modified allergen can also be used as a diagnostic to characterize the patient's allergies, using techniques such as those described in the examples.

Modifications and variations of the methods and compositions described herein are intended to be within the scope of the following claims.

Other Embodiments

Those of ordinary skill in the art will readily appreciate that the foregoing represents merely certain preferred embodiments of the invention. Various changes and modifications to the procedures and compositions described above can be made without departing from the spirit or scope of the present invention, as set forth in the following claims.

Examples

Material and Methods

For general methods used to express proteins in microorganisms see Ausubel et al. (supra) and Sambrook et al. (supra) both of which are incorporated herein by reference. In addition, expression vectors for use in the present invention are widely available from commercial sources (see for example, Clontech, Palo Alto, CA; Invitrogen, Carlsbad, CA; Promega Corporation, Madison, WI; New England Biolabs, Beverly, MA).

The following experiments describe the encapsulation of allergens in bacteria for use as a delivery vehicle and/or adjuvant in immunotherapy in accordance with the teachings of the present invention. Recombinant peanut allergen proteins (Ara h 1, Ara h 2, and Ara h 3; Burks et al. *J Allergy Clin Immunol.* 88(2):172-9, 1991; Burks et al. *J Allergy Clin Immunol.* 90(6 Pt 1):962-9, 1992; Rabjohn et al. *J Clin Invest.* 103(4):535-42, 1999; incorporated herein by reference) were produced in *E. coli* BL21 cells by transforming the bacterial cells with cDNA clones encoding the proteins (see Appendix B; sequences cloned into pET24, Novagen, Madison, WI). The transformed cells were then injected into C3H/HEJ mice to determine if the allergen-expressing *E. coli* elicited an immune response.

Example 1. Methods of killing allergen-producing *E. coli*

Several methods of killing allergen-producing *E. coli* were tested. Preferably, the method
5 of killing bacteria does not denature or proteolyze the recombinant allergen(s) produced by the
bacteria. As non-limiting examples, *E. coli* were killed by heat (at temperatures ranging from 37
°C to 95 °C), by using ethanol (0.1% to 10%), and by using solutions containing iodine (0.1% to
10%). Survival was determined by plating 100 µl of cells onto the appropriate agar plates, and
subsequently counting the resulting colonies. The most reproducible method was heat killing.
10 Therefore, the preferred method of killing allergen-producing *E. coli* is to incubate the cells at 60
°C for 20 minutes which results in 100% death (i.e. no colonies formed; see Figure 1).

Example 2. Growth of Bacteria.

15 The following protocol was developed for the preparation of allergen-producing *E. coli*
cells for inoculation of mice.

DAY 1

Five milliliters (ml) of liquid cultures of LB (Luria-Bertani broth) containing kanamycin
20 (30 micrograms/ml per each cell line used) were prepared in 50 ml sterile tubes or flasks.
Cultures were inoculated with approximately 10 microliters from a frozen stock of the desired
bacterial cell line containing the desired expression vectors. The inoculated cultures were
incubated with shaking overnight at 37 °C.

DAY 2

The following morning, 100 ml of liquid LB (500 ml Erlenmeyer flask) containing
kanamycin (30 micrograms/ml) were inoculated using a 1 ml aliquot from the 5 ml culture
grown from the previous day. (The remaining 4 mls of culture were frozen. Optionally, the
remaining 4 milliliters of culture can be stored at 4 °C for several weeks for inoculating

subsequent cultures) The inoculated cultures were incubate with shaking at 37 °C until the optical density of the solution measured at 600 nM (OD₆₀₀) reached approximately 0.6 to 0.9.

DAY 3

To induce production of recombinant proteins, the cultures from the previous day were induced by adding isopropyl-beta-D-thiogalactopyranoside (IPTG; Sigma-Aldrich, St. Louis, MO) from a 1 M stock to a final concentration of 1 mM (100 microliters of 1 M IPTG per 100 mls of culture) when the OD₆₀₀ of the culture reached approximately 0.6-0.9. The induced cultures were incubated overnight.

DAY 4

1.4 ml of culture from the previous day were aliquoted into each of five 1.5 ml microfuge tubes for each culture and heat killed at 60°C in a water bath for 20 minutes. The tubes were centrifuged at 16,000 x g for 5 minutes at room temperature and the supernatant discarded. The pellets were washed with 1X phosphate buffer saline (PBS) and centrifuged at 16,000 x g for 5 minutes at room temperature. Again, the supernatant was discarded and the pellets were resuspended in 250 microliters of 1X PBS. The resuspended pellets from the same original samples were combined. The OD₆₀₀ were determined for each sample and diluted to the desired OD₆₀₀ using 1X PBS.

Example 3. Production and release of allergen.

Release of allergen by heat-killed bacteria

In order to determine if the cells remained intact after heat-killing we measured the amount of allergen released into the media. A dot-blot assay was developed that utilized as controls, purified recombinant allergens applied to a filter at known concentrations and serum IgE from peanut sensitive patients. The assay detected and quantified the amount of allergen present in 100 microliters of supernatant after pelleting heat-killed bacteria. The level of

allergen released varied and was dependent on the expression vector and protein tested. In general, more Ara h 2 was released than Ara h 1 and Ara h 3 (Ara h 2>>Ara h 1>Ara h 3).

Production of allergen.

In order to measure amounts of allergen in *E. coli*, we developed an immunoblot assay that utilizes a six histidine tag (HIS tag) that is present on all of our purified recombinant allergens and a HIS tag antibody to build a standard curve that could then be used to estimate amounts of allergen produced. The amount of allergen produced on a per cell basis varied depending on which clone was tested. In general, more Ara h 3 was produced than Ara h 2 and Ara h 1 (Ara h 3>Ara h 2>>Ara h 1).

Our best estimates for amounts of allergen delivered in 100 µl of a 2.0 O.D. inoculum of *E. coli* varies from about 1 µg of Ara h 1 to about 20 µg of Ara h 3.

Figure 2 is an example of a standard curve generated for Ara h 2. The optical density (O.D.) of the HIS-tagged Ara h 2 allergen is then determined from an immunoblot where different concentrations of *E. coli* extract has been electrophoresed on SDS-PAGE gels. The allergen O.D. is then used to estimate the amount of protein produced by that extract.

Example 4. Immune response of mice.

The following protocol was utilized to determine the immune response of mice injected with allergen-producing bacteria. Blood was collected from the tail vein of each mouse used before the first injection. Enough blood was collected for antibody ELISA for each allergen and *E. coli* proteins. On Day Zero each mouse was injected with 100 microliters of the killed *E. coli* samples subcutaneously in the left hind flank. The mice were injected for the second time on Day 14 using the same procedure as Day Zero. On Day 21, a second blood sample was collected from each mouse. Blood samples at Day 0 and Day 21 were assayed for IgG1 and IgG2a antibodies to either Ara h 1, Ara h 2, or Ara h 3 by an ELISA assay.

Mice injected with *E. coli* producing Ara h 1 did not give detectable levels of any

immunoglobulin to the Ara h 1 allergen and therefore, that data are not shown. Without limitation to theory, we speculate that this may be due to the relatively small amounts of Ara h 1 produced by these cells (see previous discussion). Mice injected with *E. coli* producing Ara h 2 contained relatively high levels of IgG1 and IgG2a. Again, without limitation to the cause, we speculated that this may be due to the amount of Ara h 2 released from these cells (see discussion above). Mice injected with *E. coli* producing Ara h 3 contained relatively high levels of IgG2a (indicative of a Th1-type response) and elicited relatively low levels of IgG1 (indicative of a Th2-type response).

10 *Interpretation of results*

The present data should be cautiously interpreted. The data in the Figures only represent O.D. levels and do not represent absolute amounts of immunoglobulin. Therefore comparisons between groups should take into consideration the data presented as O.D. However, the general trend suggests that for example, more mice exhibited an IgG2a response to Ara h 3 than mice that exhibit an IgG1 response to Ara h 3.

EXAMPLES 5-9

Peanut allergy is one of the most common and serious of the immediate hypersensitivity reactions to foods in terms of persistence and severity of reaction. Unlike the clinical symptoms of many other food allergies, the reactions to peanuts are rarely outgrown, therefore, most diagnosed children will have the disease for a lifetime (Sampson, H.A., and Burks, A.W. (1996) *Annu. Rev. Nutr.* 16, 161-77; Bock, S.A. (1985) *J. Pediatr.* 107, 676-680). The majority of cases of fatal food-induced anaphylaxis involve ingestion of peanuts (Sampson et al., (1992) *NEJM* 327, 380-384; Kaminogawa, S. (1996) *Biosci. Biotech. Biochem.* 60, 1749-1756). The only effective therapeutic option currently available for the prevention of a peanut hypersensitivity reaction is food avoidance. Unfortunately, for a ubiquitous food such as a peanut, the possibility of an inadvertent ingestion is great.

The examples described below demonstrate identification, modification, and assessment

of allergenicity of the major peanut allergens, Ara h 1, Ara h 2, and Ara h 3. Detailed experimental procedures are included for Example 1. These same procedures were used for Examples 2-5. The nucleotide sequences of Ara h 1, Ara h 2, and Ara h 3, are shown in SEQ ID NOs. 1, 3, and 5, respectively. The amino acid sequences of Ara h 1, Ara h 2, and Ara h 3 are shown in SEQ ID NOs. 2, 4, and 6 respectively.

Example 5: Identification of linear IgE binding epitopes.

Due to the significance of the allergic reaction and the widening use of peanuts as protein extenders in processed foods, there is increasing interest in defining the allergenic proteins and exploring ways to decrease the risk to the peanut-sensitive individual. Various studies over the last several years have identified the major allergens in peanuts as belonging to different families of seed storage proteins (Burks, et al. (1997) *Eur. J. Biochem.* 245, 334-339; Stanley, et al. (1997) *Arch. Biochem. Biophys.* 342, 244-253). The major peanut allergens Ara h 1, Ara h 2, and Ara h 3 belong to the vicilin, conglutin and glycinin families of seed storage proteins, respectively. These allergens are abundant proteins found in peanuts and are recognized by serum IgE from greater than 95% of peanut sensitive individuals, indicating that they are the major allergens involved in the clinical etiology of this disease (Burks, et al. (1995) *J. Clinical Invest.*, 96, 1715-1721). The genes encoding Ara h 1 (SEQ ID NO. 1), Ara h 2 (SEQ ID NO. 3), and Ara h 3 (SEQ ID NO. 5) and the proteins encoded by these genes (SEQ ID NOs. 2, 4, 6) have been isolated and characterized. The following studies were conducted to identify the IgE epitopes of these allergens recognized by a population of peanut hypersensitive patients and a means for modifying their affinity for IgE.

Experimental Procedures

Serum IgE. Serum from 15 patients with documented peanut hypersensitivity reactions (mean age, 25 yrs) was used to determine relative binding affinities between wild-type and mutant Ara h 1 synthesized epitopes. The patients had either a positive double-blind, placebo-controlled, food challenge or a convincing history of peanut anaphylaxis (laryngeal edema, severe wheezing, and/or hypotension; Burks, et al. (1988) *J. Pediatr.* 113, 447-451). At least 5

ml of venous blood was drawn from each patient, allowed to clot, and serum was collected. A serum pool from 12 to 15 patients was made by mixing equal aliquots of serum IgE from each patient. The pools were then used in immunoblot analysis.

Peptide synthesis. Individual peptides were synthesized on a derivatized cellulose membrane using 9-fluorenylmethoxycarbonyl (Fmoc) amino acid active esters according to the manufacturer's instructions (Genosys Biotechnologies, Woodlands, Texas; Fields, G.B and Noble, R.L. (1990) *Int. J. Peptide Protein Res.* 35, 161-214). Fmoc-amino acids (N-terminal blocked) with protected side chains were coupled in the presence of 1-methyl-2-pyrrolidone to a derivatized cellulose membrane. Following washing with dimethylformamide (DMF), unreacted terminal amino groups were blocked from further reactions by acetylation with acetic anhydride. The N-terminal Fmoc blocking group was then removed by reaction with 20% piperidine and 80% DMF, v/v. The membrane was washed in DMF followed by methanol, the next reactive Fmoc-amino acid was then coupled as before, and the sequence of reactions was repeated with the next amino acid. When peptide synthesis was complete, the side chains were deprotected with a mixture of dichloromethane (DCM), trifluoroacetic acid, and triisobutylsilane (1.0:1.0:0.5), followed by successive washes in DCM, DMF, and methanol. Peptides synthesis reactions were monitored by bromophenol blue color reactions during certain steps of synthesis. Cellulose derivitised membranes and Fmoc-amino acids were supplied by Genosys Biotechnologies. All other chemical were purchased from Aldrich Chemical Company, Inc. (Milwaukee, WI) or Fluka (Bucks, Switzerland). Membranes were either probed immediately or stored at -20°C until needed.

IgE binding assays. Cellulose membranes containing synthesized peptides were washed 3 times in Tris-buffered saline (TBS; 136 mM NaCl, 2.7 mM KCl, and 50 mM trizma base pH 8.0) for 10 min at room temperature (RT) and then incubated overnight in blocking buffer: [TBS, 0.05% TweenTM 20; concentrated membrane blocking buffer supplied by Genosys; and sucrose (0.0:1.0:0.5)]. The membrane was then incubated in pooled sera diluted in 1:5 in 20 mM Tris-Cl pH7.5, 150 mM NaCl, and 1% bovine serum albumin overnight at 4°C. Primary antibody was detected with ¹²⁵I-labeled equine anti-human IgE (Kallestad, Chaska, MN).

Quantitation of IgE binding. Relative amounts of IgE binding to individual peptides

were determined by a Bio-Rad (Hercules, CA) model GS-700 imaging laser densitometer and quantitated with Bio-Rad molecular analyst software. A background area was scanned and subtracted from the obtained values. Following quantitation, wild-type intensities were normalized to a value of one and the mutants were calculated as percentages relative to the wild-type.

Synthesis and purification of recombinant Ara h 2 protein. cDNA encoding Ara h 2 was placed in the pET-24b expression vector. The pET-24 expression vector places a 6 x histidine tag at the carboxyl end of the inserted protein. The histidine tag allows the recombinant protein to be purified by affinity purification on a nickel column (HisBind resin). Recombinant Ara h 2 was expressed and purified according to the instructions of the pET system manual. Briefly, expression of the recombinant Ara h 2 was induced in 200 ml cultures of strain BL21(DE3) E. coli with 1 mM IPTG at mid log phase. Cultures were allowed to continue for an additional 3 hours at 36°C. Cells were harvested by centrifugation at 2000 x g for 15 minutes and then lysed in denaturing binding buffer (6 M urea, 5 mM imidazole, 0.5 M NaCl, 20 mM Tris-HCl, pH 7.9). Lysates were cleared by centrifugation at 39,000 x g for 20 minutes followed by filtration through 0.45 micron filters. The cleared lysate was applied to a 10 ml column of HisBind resin, washed with imidazole wash buffer (20 mM imidazole, 6 M urea, 0.5 M NaCl, 20 mM Tris-HCl, pH 7.9). The recombinant Ara h 2 was then released from the column using elution buffer (1 M imidazole, 0.5 M NaCl, 20 mM Tris-HCl, pH 7.9). The elution buffer was replaced with phosphate buffered saline by dialysis. The purification of recombinant Ara h 2 was followed by SDS PAGE and immunoblots. Peanut specific serum IgE was used as a primary antibody.

Skin prick tests. The ability of purified native and recombinant Ara h 2 to elicit the IgE mediated degranulation of mast cells was evaluated using prick skin tests in a peanut allergic individual. An individual meeting the criteria for peanut allergy (convincing history or positive double blind placebo controlled food challenge) and a non-allergic control were selected for the testing. Purified native and recombinant Ara h 2 and whole peanut extract (Greer Laboratories, Lenoir, N.C) were tested. Twenty microliters of the test solution were applied to the forearm of the volunteer and the skin beneath pricked with a sterile needle. Testing was started at the lowest

concentration (less than or equal to 1 mg/ml) and increased ten fold each round to the highest concentration or until a positive reaction was observed. Mean diameters of the wheal and erythema were measured and compared to the negative saline control. A positive reaction was defined as a wheal 3mm larger than the negative control. Histamine was used as the positive control.

Results

Identification of the linear IgE-binding epitopes of Ara h 1, Ara h 2 and Ara h 3 allergens. Epitope mapping was performed on the Ara h 1, Ara h 2 and Ara h 3 allergens by synthesizing each of these proteins in 15 amino acid long overlapping peptides that were offset from each other by 8 amino acids. The peptides were then probed with a pool of serum IgE from 15 patients with documented peanut hypersensitivity. This analysis resulted in multiple IgE binding regions being identified for each allergen. The exact position of each IgE binding epitope was then determined by re-synthesizing these IgE reactive regions as 10 or 15 amino acid long peptides that were offset from each other by two amino acids. These peptides were probed with the same pool of serum IgE from peanut sensitive patients as used before. An example of this procedure for each of the peanut allergens is shown in Figures 5-7. Figure 5 depicts twenty-two 10-mer peptides (SEQ ID NOs. 45-66) that span amino acid residues 82-133 (SEQ ID NO. 44) of the Ara h 1 allergen (SEQ ID NO. 2). This region of the Ara h 1 allergen includes epitopes 4, 5, 6, and 7, as identified in Table 1. Figure 6 depicts seven 10-mer peptides (SEQ ID NOs. 68-74) that span amino acid residues 55-76 (SEQ ID NO. 67) of the Ara h 2 allergen (SEQ ID NO. 4). This region of the Ara h 2 allergen includes epitopes 6 and 7 as identified in Table 2. Figure 7 depicts six 15-mer peptides (SEQ ID NOs. 76-81) that span amino acid residues 299-321 (SEQ ID NO. 75) of the Ara h 3 allergen (SEQ ID NO. 6). This region of the Ara h 3 allergen includes epitope 4 as identified in Table 3. This analysis revealed that there were 23 linear IgE binding epitopes on Ara h 1, 10 epitopes on Ara h 2, and 4 epitopes on Ara h 3.

In an effort to determine which, if any, of the epitopes were recognized by the majority of patients with peanut hypersensitivity, each set of epitopes identified for the peanut allergens were

synthesized and then probed individually with serum IgE from 10 different patients. All of the patient sera tested recognized multiple epitopes.

Table 1 shows the amino acid sequence and position of each epitope within the Ara h 1 protein (SEQ ID NO. 2) of all 23 IgE binding epitopes mapped to this molecule. Table 2 shows
5 the amino acid sequence and position of each epitope within the Ara h 2 protein (SEQ ID NO. 4) of all 10 IgE binding epitopes mapped to this molecule. Table 3 shows the amino acid sequence and position of each epitope within the Ara h 3 protein (SEQ ID NO. 6) of all 4 IgE binding epitopes mapped to this molecule.

10 Four epitopes of the Ara h 1 allergen (peptides 1, 3, 4, 17 of Table 1), three epitopes of the Ara h 2 allergen (peptides 3, 6, 7 of Table 2), and one epitope of the Ara h 3 allergen (peptide 2 of Table 3) were immunodominant.

Example 6: Modification of peanut allergens to decrease allergenicity.

The major linear IgE binding epitopes of the peanut allergens were mapped using overlapping peptides synthesized on an activated cellulose membrane and pooled serum IgE from 15 peanut sensitive patients, as described in Example 1. The size of the epitopes ranged from six to fifteen amino acids in length. The amino acids essential to IgE binding in each of the epitopes were determined by synthesizing duplicate peptides with single amino acid changes at each position. These peptides were then probed with pooled serum IgE from 15 patients with peanut hypersensitivity to determine if the changes affected peanut-specific IgE binding. For example, epitope 9 in Table 1 was synthesized with an alanine or methionine residue substituted for one of the amino acids and probed. The following amino acids were substituted (first letter is the one-letter amino acid code for the residue normally at the position, the residue number, followed by the amino acid that was substituted for this residue; the numbers indicate the position of each residue in the Ara h 1 protein, SEQ ID NO. 2): Q143A, P144A; R145A; K146A; I147A; R148A; P149A; E150A; G151A; R152A; Q143M; P144M; R145M; K146M; I147M; R148M; P149M; E150M; G151M; R152M. The immunoblot strip containing the wild-type and mutated peptides of epitope 9 showed that binding of pooled serum IgE to individual peptides was dramatically reduced when either alanine or methionine was substituted for each of the amino acids at positions 144, 145, and 147-150 of Ara h 1 shown in SEQ ID NO. 2. Changes at positions 144, 145, 147, and 148 of Ara h 1 shown in SEQ ID NO. 2 had the most dramatic

effect when methionine was substituted for the wild-type amino acid, resulting in less than 1% of peanut specific IgE binding to these peptides. In contrast, the substitution of an alanine for arginine at position 152 of Ara h 1 shown in SEQ ID NO. 2 resulted in increased IgE binding. The remaining Ara h 1 epitopes, and the Ara h 2 and Ara h 3 epitopes, were tested in the same manner and the intensity of IgE binding to each spot was determined as a percentage of IgE binding to the wild-type peptide. Any amino acid substitution that resulted in less than 1% of IgE binding when compared to the wild-type peptide was noted and is indicated in Tables 4-6. Table 4 shows the amino acids that were determined to be critical to IgE binding in each of the Ara h 1 epitopes. Table 5 shows the amino acids that were determined to be critical to IgE binding in each of the Ara h 2 epitopes. Table 6 shows the amino acids that were determined to be critical to IgE binding in each of the Ara h 3 epitopes.

This analysis indicated that each epitope could be mutated to a non-IgE binding-peptide by the substitution of a single amino acid residue.

The results discussed above for Ara h 1, Ara h 2, and Ara h 3 demonstrate that once an IgE binding site has been identified, it is possible to reduce IgE binding to this site by altering a single amino acid of the epitope. The observation that alteration of a single amino acid leads to the loss of IgE binding in a population of peanut-sensitive individuals is significant because it suggests that while each patient may display a polyclonal IgE reaction to a particular allergen, IgE from different patients that recognize the same epitope must interact with that epitope in a similar fashion. Besides finding that many epitopes contained more than one residue critical for IgE binding, it was also determined that more than one residue type (ala or met) could be substituted at certain positions in an epitope with similar results. This allows for the design of a hypoallergenic protein that would be effective at blunting allergic reactions for a population of peanut sensitive individuals. Furthermore, the creation of a plant producing a peanut where the IgE binding epitopes of the major allergens have been removed should prevent the development of peanut hypersensitivity in individuals genetically predisposed to this food allergy.

<u>1</u>	IETWN <u>P</u> N <u>N</u> QEFECAG	<u>33-47</u>	<u>40</u>
<u>2</u>	GNI <u>F</u> SG <u>F</u> T <u>P</u> E <u>F</u> L <u>E</u> Q <u>A</u>	<u>240-254</u>	<u>41</u>
<u>3</u>	VTVRG <u>G</u> L <u>R</u> ILSPDRK	<u>279-293</u>	<u>42</u>
<u>4</u>	DEDEY <u>E</u> <u>Y</u> DE <u>E</u> <u>D</u> RRRG	<u>303-317</u>	<u>43</u>

The Ara h 3 IgE binding epitopes are indicated as the single letter amino acid code. The position of each peptide with respect to the Ara h 3 protein (SEQ ID NO. 6) is indicated. The amino acids that, when altered, lead to loss of IgE binding are shown as the bold, underlined. All of these sequences can be found in SEQ ID NO. 6.

Example 7: A modified Ara h 2 protein binds less IgE but similar amounts of IgG.

In order to determine the effect of changes to multiple epitopes within the context of the intact allergen, four epitopes (including the three immunodominant epitopes) of the Ara h 2 allergen were mutagenized and the protein produced recombinantly. The amino acids at position 20, 31, 60, and 67 of the Ara h 2 protein (shown in SEQ ID NO. 4) were changed to alanine by mutagenizing the gene encoding this protein by standard techniques. These residues are located in epitopes 1, 3, 6, and 7 and represent amino acids critical to IgE binding that were determined in Example 2. The modified and wild-type versions of this protein were produced and immunoblot analysis performed using serum from peanut sensitive patients. These results showed that the modified version of this allergen bound significantly less IgE than the wild-type version of these recombinant proteins but bound similar amounts of IgG.

Example 8: A modified Ara h 2 protein retains the ability to stimulate T cells to proliferate.

The modified recombinant Ara h 2 protein described in Example 3 was used in T cell

proliferation assays to determine if it retained the ability to activate T cells from peanut sensitive individuals. Proliferation assays were performed on T cell lines grown in short-term culture developed from six peanut sensitive patients. T cells lines were stimulated with either 50 µg of crude peanut extract, 10 µg of native Ara h 2, 10 µg of recombinant wild-type Ara h 2, or 10 µg of modified recombinant Ara h 2 protein and the amount of 3H-thymidine determined for each cell line. Results were expressed as the average stimulation index (SI) which reflected the fold increase in 3H-thymidine incorporation exhibited by cells challenged with allergen when compared with media treated controls (Figure 8).

Example 9: A modified Ara h 2 protein elicits a smaller wheal and flare in skin prick tests of a peanut sensitive individual.

The modified recombinant Ara h 2 protein described in Example 3 and the wild-type version of this recombinant protein were used in a skin prick test of a peanut sensitive individual. Ten micrograms of these proteins were applied separately to the forearm of a peanut sensitive individual, the skin pricked with a sterile needle, and 10 minutes later any wheal and flare that developed was measured. The wheal and flare produced by the wild-type Ara h 2 protein (8 mm X 7 mm) was approximately twice as large as that produced by the modified Ara h 2 protein (4 mm X 3 mm). A control subject (no peanut hypersensitivity) tested with the same proteins had no visible wheal and flare but, as expected, gave positive results when challenged with histamine. In addition, the test subject gave no positive results when tested with PBS alone. These results indicate that an allergen with only 40% of its IgE binding epitopes modified (4/10) can give measurable reduction in reactivity in an *in vivo* test of a peanut sensitive patient.

These same techniques can be used with the other known peanut allergens, Ara h 1 (SEQ ID NOs. 1 and 2), Ara h 3 (SEQ ID NOs. 5 and 6), or any other allergen.

Modifications and variations of the methods and materials described herein will be obvious to those skilled in the art. Such modifications and variations are intended to come within the scope of the appended claims.

We claim:

Claims

1. A method of treating an allergy in a subject susceptible to an anaphylactic allergic response to an allergen, the method comprising steps of:

5 providing a composition comprising microorganisms that produce the allergen; and administering the composition to the subject at an effective and non-toxic dose.

2. The method of claim 1, wherein in the step of providing, the microorganism is selected from the group consisting of: bacteria, fungi, viruses, algae, and protozoa.

10 3. The method of claim 1, wherein in the step of providing, the microorganism is selected from the group consisting of: gram-negative bacteria, gram-positive bacteria, and yeast.

4. The method of claim 1, wherein in the step of providing, the microorganism is selected from the group consisting of: *E. coli*, *Lactococcus*, *Listeria*, *Vibrio*, *Salmonella* and *S. cerevisiae*.

15 5. The method of claim 1, wherein in the step of providing, the allergen is found in foods, venoms, or latex.

20 6. The method of claim 1, wherein in the step of providing, the allergen is a protein found in peanuts, milk, eggs, seafood, nuts, dairy products and fruit.

7. The method of claim 1, wherein in the step of providing, the allergen is a protein found in bee venom.

25 8. The method of claim 1, wherein in the step of providing, the allergen is Ara h 1, Ara h 2, Ara h 3, or a polypeptide portion thereof.

9. The method of claim 1, wherein in the step of providing, the allergen is protein modified

to have a reduced ability to bind and crosslink IgE antibodies.

10. The method of claim 1, wherein in the step of providing, the microorganisms produce a portion of the allergen.

5 11. The method of claim 10, wherein in the step of providing, the portion of the allergen produced has a reduced number of IgE binding sites as compared to the allergen.

10 12. The method of claim 1, wherein in the step of providing, the allergen is a polypeptide and production of the allergen is inducible; and wherein after the step of administering, the method further comprises the step of inducing expression of the polypeptide.

13. The method of claim 12, wherein in the step of inducing, the polypeptide is secreted into a periplasm or secreted outside the cell.

15 14. The method of claim 1, wherein the step of providing comprises providing a composition comprising gram-negative bacteria or yeast that secretes the allergen into a periplasm.

15. The method of claim 1, wherein in the step of providing, the allergen is a small molecule.

20 16. A composition comprising a microorganism that produces an allergen that elicits an anaphylactic allergic reaction in a subject allergic to the allergen.

17. The composition of claim 16, wherein the allergen is a polypeptide or small molecule.

25 18. The composition of claim 16, wherein the microorganism is selected from the group consisting of: bacteria, fungi, viruses, algae, and protozoa.

19. The composition of claim 16, wherein the microorganism is selected from the group

consisting of: gram-negative bacteria, gram-positive bacteria, and yeast.

20. The composition of claim 16, wherein the microorganism is selected from the group consisting of: *E. coli*, *Lactococcus*, *Listeria*, *Vibrio*, *Salmonella* and *S. cerevisiae*

5

21. The composition of claim 16, wherein the allergen found in foods, venoms, or latex.

22. The composition of claim 16, wherein the allergen is an allergen found in peanuts, milk, eggs, seafood, nuts, dairy products and fruit.

10

23. The composition of claim 16, wherein the allergen found in bee venom.

24. The composition of claim 16, wherein the protein is Ara h 1, Ara h 2, Ara h 3, or a polypeptide portion thereof.

15

25. The composition of claim 16, wherein the allergen is modified to have a reduced ability to bind and crosslink IgE antibodies.

26. The composition of claim 16, wherein the microorganism produces a portion of the allergen.

20

27. The composition of claim 16, wherein the portion of the allergen produced has a reduced number of IgE binding sites as compared to the allergen.

25 28. The composition of claim 16, wherein production of the allergen is inducible.

29. The composition of claim 16, wherein the allergen is a polypeptide which is secreted into a periplasm or secreted outside the cell.

30. The composition of claim 16, wherein the microorganism is a gram-negative bacteria or yeast that secretes the allergen into a periplasm.

31. A pharmaceutical composition comprising microorganisms that produce an allergen that
5 elicits an anaphylactic allergic response in a subject susceptible to the anaphylactic allergic response, and further comprises a pharmaceutically acceptable carrier.

32. The pharmaceutical composition of claim 31, wherein the allergen is a polypeptide or a small molecule.

10 33. The pharmaceutical composition of claim 31, wherein the microorganisms produce a portion of an allergen that elicits an anaphylactic allergic response in a subject susceptible to the anaphylactic allergic response.

Abstract

The present invention provides methods and compositions for treating or preventing allergic responses, particularly anaphylactic allergic responses, in subjects who are allergic to allergens or susceptible to allergies. Methods of the present invention utilize administration of microorganisms to subjects, where the microorganisms produce allergens and protect the subjects from exposure to the allergens until phagocytosed by antigen-presenting cells. Particularly preferred microorganisms are gram-negative bacteria, gram-positive bacteria, and yeast. Particularly preferred allergens are proteins found in foods, venoms, drugs and latex that elicit allergic reactions and anaphylactic allergic reactions in individuals who are allergic to the proteins or are susceptible to allergies to the proteins. The proteins may also be modified to reduce the ability of the proteins to bind and crosslink IgE antibodies and thereby reduce the risk of eliciting anaphylaxis without affecting T-cell mediated Th1-type immunity.
